## Foreword

This is the documentation of the Frama-C implementation (available at http://frama-c. cea.fr) which aims to help any developer to integrate a new plug-in inside this platform. It was first a deliverable of the task 2.3 of the ANR RNTL project CAT (http://www.rntl. org/projet/resume2005/cat.htm).

The content of this document corresponds to the version Beryllium-20090601-beta1 (June 23, 2009) of Frama-C. However the development of Frama-C is still ongoing: several features described here may still evolve in the future.

## Acknowledgements

We gratefully thank all the people who contributed to this document: Patrick Baudin, Richard Bonichon, Loïc Correnson, Pascal Cuoq, Pierre-Loïc Garoche, Nikolaï Kosmatov, Benjamin Monate, Yannick Moy and Anne Pacalet. We also gratefully thank Johannes Kanig for his initiation to Mlpost<sup>1</sup>, the tool used for making the figures of this document.

# Chapter 1 Introduction

This guide aims at helping any developer to program within the Frama-C platfom, in particular for developing a new analysis or a new source-to-source transformation through a new plug-in. For this purpose, it provides a step-by-step tutorial, a general presentation of the Frama-C software architecture, a set of Frama-C-specific programming rules and an overview of the API of the Frama-C kernel. However it does not provide a complete documentation of the Frama-C plug-ins. This API and, in particular, it does not describe the API of existing Frama-C plug-ins. This API is documented in the html source code generated by make doc (see Section 4.17.1 for additional details about this documentation).

The reader of this guide may be either a Frama-C beginner who wishes to develop his/her own analysis with the help of Frama-C, or an intermediate-level plug-in developer who wants to better understand one particular aspect of the framework, or a Frama-C expert who aims to remember details about one specific point of the Frama-C development.

**About this document** In order to ease the reading, beginning of sections may state the category of readers it is intended for and a set of prerequisites.

Appendix A references all the changes made to this document between successive Frama-C releases.

In the index, page numbers written like 1 reference the defining sections for the corresponding entries while other numbers (like 1) are less important references. Furthermore, the name of each OCaml value in the index corresponds to an actual Frama-C value. In the Frama-C source code, the ocamldoc documentation of such a value contains the special tag @plugin development guide while, in the html documentation of the Frama-C API, the note "Consult the Plugin Development Guide for additional details" is attached the value name.

Most important paragraphs are displayed inside a gray box like this one. A plug-in developer **must** follow them very carefully.

There are numbers pieces of code written in this document. Do not copy/paste them from the PDF to your favorite text editor because the PDF text may contain non-ASCII characters prevented the code to compile.

**Outline** This guide is organised in four parts. The first one, Chapter 2, is a step-by-step tutorial for developing a new plug-in within the Frama-C platform. At the end of this tutorial, a developer should be able to extend Frama-C with a simple analysis available as a Frama-C

### CHAPTER 1. INTRODUCTION

plug-in. The second part, Chapter 3, presents the design of the Frama-C software architecture. The third part, Chapter 4, details how to use all the services provided by Frama-C in order to develop a fully integrated plug-in. The fourth part, Chapter 5, is a reference manual with complete documentation for some particular points of the Frama-C platform.

# Chapter 2 Tutorial

Target readers: beginners.

This chapter aims at helping a developer to write his first Frama-C plug-in. At the end of the tutorial, any developer should be able to extend Frama-C with a simple analysis available as a Frama-C plug-in. This chapter was written to explain step-by-step how to proceed towards this goal. It will get you started but does not tell the whole story. In particular, some very important aspects for the integration in the framework are omitted here and are described in chapter 4.

Section 2.1 explains the basis for writing a standard Frama-C plug-in while section 2.2 explains the basis for writing a plug-in integrated with the Frama-C kernel: this is slightly more involved but allows a deeper integration within the Frama-C architecture. You should do this only if you intend to contribute a large and very general purpose plug-in to the community.

## 2.1 Standard Plug-in

This section will teach you how to write the most basic plug-in and run it from the Frama-C toplevel.

**Prerequisite:** To follow this tutorial:

- Frama-C needs to be installed in your path;
- the Objective Caml compilers must be installed in your path. These must be the same compilers as the ones you used to compile Frama-C<sup>1</sup>;
- GNU make must be in your path.

### 2.1.1 Plug-in Integration Overview

Figure 2.1 shows how a can integrate with the Frama-C platform. This tutorial focuses on some parts only of this figure.

 $<sup>^{1}</sup>$ If you have an Objective Caml version <3.11 then only bytecode plug-ins are available. Upgrade to Objective Caml >=3.11 if you need native code plug-ins.

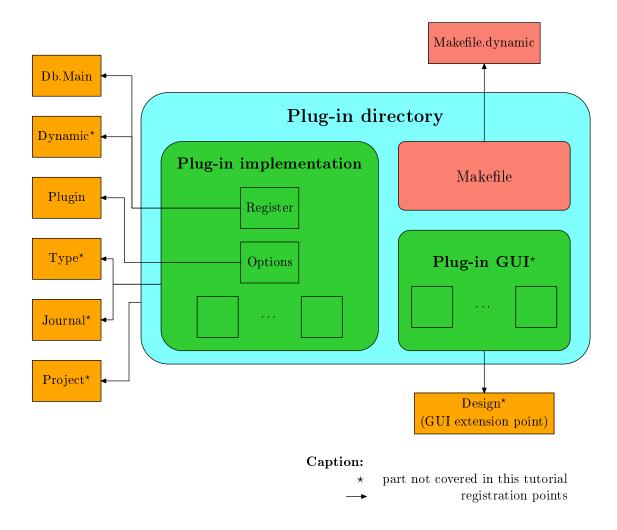

Figure 2.1: Plug-in Integration Overview.

The implementation of the plug-in is provided inside a specific directory. The plug-in registers with the Frama-C platform through kernel-provided registration points. These registrations are performed through hooks (by applying a function or a functor). For instance, the next section shows how to:

- extend the Frama-C entry point thanks to the function Db.Main.extend if you want to run plug-in specific code whenever Frama-C is executed;
- use specific plug-in services provided by the module Plugin as adding a new Frama-C option.

### 2.1.2 Hello Frama-C World

A very basic plug-in is the 'Hello World' plug-in. This plug-in adds a command line option -hello to Frama-C and pretty prints the message 'Hello World!' whenever the option is set. It is possible to program such an option just with the module Arg provided by the Objective Caml standard library and without the addition of a Frama-C plug-in, but we use this example to introduce the bases of plug-in development. This plug-in is our running example in this chapter.

The 'Hello World' plug-in consists of only two files: Makefile and hello\_world.ml<sup>2</sup>.

1. Create the two files Makefile and hello\_world.ml containing the lines given in the frames at the end of this section.

The name of each compilation unit (here hello\_world) must be different of the plug-in name set by the Makefile (here Hello) in order to compile a plug-in.

- 2. Run make to compile it.
- 3. Run make install to install the plug-in. You need to have write access to the \$(FRAMAC\_LIBDIR)/plugins directory.
- 4. Test your plug-in with frama-c.byte -hello. The sentence 'Hello Frama-C World!' is printed.

File Makefile

File hello world.ml

```
(** The traditional 'Hello world!' plugin.
    It contains one boolean state [Enabled] which can be set by the
   command line option "-hello".
    When this option is set it just pretty prints a message on the standard
    output. *)
(** Register the new plug-in "Hello World" and provide access to some plug-in
    dedicated features. *)
module Self =
  Plugin. Register
   (struct
       |et name = "Hello world"
       let shortname = "hello"
       let descr = "The famous 'Hello world' plugin"
     end)
(** Register the new Frama-C option "-hello". *)
module Enabled =
  Self.False
    (struct
       let option name = "-hello"
       let descr = "pretty print \"Hello world!\""
     end)
(** Print 'Hello World!' whenever the option is set. *)
let run () = if Enabled.get () then Self.result "Hello world!"
(** The code below is not mandatory: you can ignore it in a first reading. It
    provides an API for the plug-in, so that the function [run] is callable by
```

<sup>2</sup>Both files are distributed within Frama-C and they are available from the directory src/dummy/hello\_world of the source distribution.

## 2.2 Kernel-integrated Plug-in

Target readers: It is only for:

- beginners which have to implement a plug-in requiring a very deep integration within the Frama-C architecture;
- new Frama-C-kernel developers.

**Prerequisite:** Getting the Frama-C source.

This section will teach you how to write the most basic kernel-integrated plug-in and run it from the Frama-C toplevel. This plug-in will be linked with the Frama-C kernel and with all the other kernel-integrated plug-ins. It is slightly more involved but allows a deeper integration within the Frama-C architecture. The running example of this section is the very same plug-in 'Hello World' than the one of the previous section.

### 2.2.1 Setup

Frama-C uses a makefile which is generated by the script configure. This script checks your system to determine the most appropriate Frama-C configuration, in particular the plug-ins that should be available. This file is itself generated by the autotool autoconf. Consequently, you have to execute the following commands:

```
$ autoconf
$ ./configure
```

This generates a proper makefile and lists the available plug-ins. Now you are able to compile sources with make.

\$ make

This compilation produces the following binaries (in a standard configuration):

- bin/toplevel.byte and bin/toplevel.opt (Frama-C toplevel);
- bin/viewer.byte and bin/viewer.opt (Frama-C GUI);
- bin/ptests.byte (Frama-C testing tool).

Suffixes .byte and .opt respectively correspond to the bytecode and native versions of binaries. If you wish, and before having fun with Frama-C, you can:

- test the compiled platform with make tests;
- generate the source documentation with make doc;
- generate navigation tags for emacs with make tags.

### 2.2.2 Plug-in Integration Overview

Figure 2.2 shows how a kernel-integrated plug-in may integrate in the Frama-C platform. Some elements of this figure are pragmatically explained in the remaining sections of this tutorial.

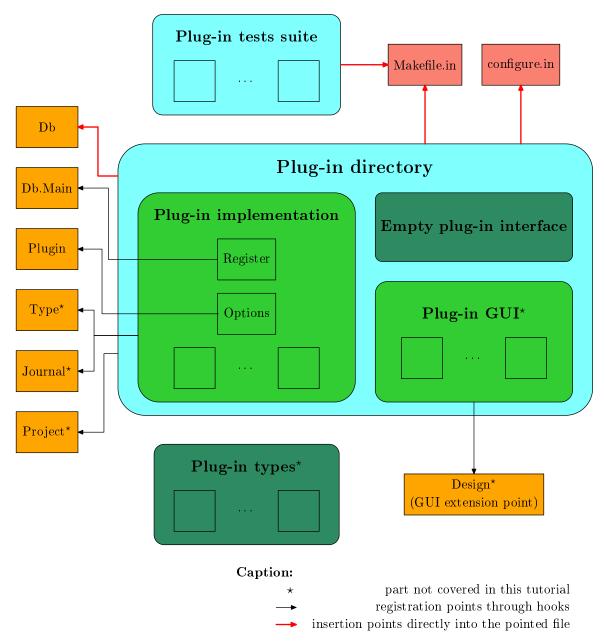

Figure 2.2: Kernel-integrated Plug-in Integration Overview.

The implementation of the plug-in is provided inside a specific directory and is connected to the Frama-C platform thanks to some registration points. These registrations are performed

#### CHAPTER 2. TUTORIAL

either through hooks (by applying a function or a functor) or directly by modifying some specific part of Frama-C files. That is the very major difference with integrating standard plug-ins: standard plug-ins never modify Frama-C files. For instance, you have to extend Db with your plug-in-specific operations and to register them inside it if you want that someone uses your plug-in (see Section 2.2.5). However most of the registration way are the same as standard plug-ins (see Section 2.1) (for instance, extending the Frama-C entry point).

You also have to modify the files Makefile.in and configure.in in order to properly link your plug-in with Frama-C (see Section 2.2.4).

Moreover, the developer may provide a plug-in interface (which should usually be empty, see Section 2.2.5) and aventually specific test suites (see Section 2.2.6).

### 2.2.3 Hello Frama-C World

This section explains how to write the core of a kernel-integrated plug-in Hello. This is a plug-in which pretty-prints 'Hello World!' whenever the option -hello is set on the Frama-C command line.

First, we add a new subdirectory hello in directory src.

\$ mkdir src/hello

This new directory is going to contain the source file of our new plug-in<sup>3</sup>. If you want, you can have a quick look at **src** which contains the kernel and existing plug-ins. We only use a few files of this directory in this tutorial.

We can now edit the source file of hello, called src/hello/register.ml. It should contain exactly the same code than the file hello\_world.ml given page 15 in Section 2.1.2: there is not a so big difference between kernel-integrated plug-ins and the other ones.

**Recommendation 2.1** In Frama-C, the name of the "main" file of a plug-in p should always be called either register.ml or  $p_{register.ml}$ .

At this point, we have a compilable plug-in made of a main function run.

### 2.2.4 Configuration and Compilation

Here we explain how to compile the plug-in hello. Section 4.2 and 4.3 provide more details about the configuration and compilation of plug-ins.

**Configuration** As explained in Section 2.2.1, Frama-C uses both autoconf and make in order to compile. Consequently, we have to modify both files configure.in and Makefile.in in order to compile our plug-in within Frama-C. In both files, some predefined scripts help with plug-in integration.

In order to compile the hello plug-in, first add the following lines into configure.in<sup>4</sup>. They indicate how to configure hello, especially whether it has to be compiled or not.

File configure.in

<sup>&</sup>lt;sup>3</sup>As the plug-in hello is tiny, it has only one source file.

<sup>&</sup>lt;sup>4</sup>In this document, a comment containing ... among lines of code represents an undisplayed piece of code written either previously in the document or by someone else.

These lines correspond to the standard scheme for configuring a new plug-in. Function check\_plugin is defined in configure.in. Its first argument is the plug-in name, the second one is the plug-in directory (the directory containing the plug-in source files), the third one is a help message, the fourth one indicates whether the plug-in is available by default (here yes says that the plug-in is available by default and a user may use option -disable-hello to disactivate the plug-in) and the last one indicates whether the plug-in will be dynamically linked within Frama-C (here no says that the plug-in will be statically linked).

Now we are ready to execute

```
$ autoconf
$ ./configure
```

and to check that the new plug-in hello is going to compile: you should have the line

```
checking for src/hello... yes
hello... yes
```

in the configuration summary.

**Compilation** Once configure.in is extended, we also have to modify Makefile.in with the following lines.

```
File Makefile.in
```

These lines use the predefined makefile Makefile.plugin which is a generic makefile dedicated to the compilation of one plug-in. There are more than twenty variables than can be used to customize the behavior of Makefile.plugin. These variables are all described in Section 5.3.3, but most of them have reasonable default values so that it is not necessary to describe more than the few above.

Now we briefly explain the variables that are set for hello.

- PLUGIN\_ENABLE indicates that the plug-in should be compiled. Here we use the variable @ENABLE\_HELLO@ set by configure.in.
- PLUGIN\_NAME is the name of the plug-in.

The variable PLUGIN\_NAME must hold a valid OCaml module name (in particular it must be capitalised).

- PLUGIN\_DIR is the directory containing the source file(s) for the plug-in.
- PLUGIN\_CMO is the list of the .cmo files (without the extension .cmo nor the plug-in path) required to compile the plug-in.
- PLUGIN\_NO\_TEST is set to yes because there is no specific test directory for the plug-in (see Section 2.2.6 about plug-in testing).

Now we are ready to compile Frama-C with the new plug-in hello.

```
$ make
```

At this point, the plug-in works properly: a Frama-C user can run the plug-in safely.

```
| $ ./bin/toplevel.byte -hello
| Hello World!
```

### 2.2.5 Connection with the Frama-C World

The plug-in hello is now compiled but it is not fully registered within the Frama-C framework. In particular, our plug-in should be added in the plug-in database Db in order to be simply used by other plug-ins (see Chapter 3 for details).

**Extension of the Plug-in Database** For this purpose, we have to extend Db with the new plug-in hello.

File src/kernel/db.mli

```
(** Hello World plug-in.
@see <.../hello/index.html> internal documentation. *)
module Hello : sig
va| run: (Format.formatter → unit) ref (** Print "hello world". *)
end
...
```

File src/kernel/db.ml

```
module Hello = struct |et run = mk_fun "Hello_world.run" end
....
```

The interface declares a new module Hello containing a single function run. Indeed run is a reference to a function. This reference is not initialised in the implementation of Db: we use mk\_fun (declared in the opened module Extlib) in order to declare the reference without instantiating it. This instantiation has to be done by the plug-in itself. Otherwise, a call to !Db.run raises the exception Extlib.NotYetImplemented. In order to fix this, we modify the module Register as follows.

```
File src/hello/register.ml
```

```
... definition of run
∣et () = Db.Hello.run ← run
```

It is important to note that the reference Db.Hello.run is set at the OCaml module initialisation step. So the body of each Frama-C function can safely dereference it. **Documentation** We have properly documented the interface of Db with ocamldoc through special comments between (\*\* and \*). This documentation is generated by make doc. In particular, this command also generates an internal documentation for hello which is accessible in the directory doc/code/hello.

Hiding the Implementation Finally, we hide the implementation of hello to other developers in order to enforce the architecture invariant which is that each plug-in should be used through Db (see Chapter 3). For this purpose we add an empty interface to the plug-in in the following way.

File src/hello/Hello.mli

```
(** Hello World plug-in.
No function is directly exported: they are registered in {!Db.Hello}. *)
```

Note the unusual capitalisation of the filename Hello.mli which is required for compilation purposes.

Indeed, thanks to Makefile.plugin, each plug-in is packed into a single module **\$(PLUGIN\_NAME)** (here Hello) and we simply export an empty interface for it.

We also have to explain to Makefile.plugin that we use our own interface hello.mli for Hello. For this purpose, in Makefile.in, we add the following line before including Makefile.plugin.

File Makefile.in

### 2.2.6 Testing

Frama-C provides a tool, called **ptests**, in order to perform non-regression and unit tests. This tool is detailed in Section 4.5. This section only covers basic use of **ptests**. First we have to create a test directory for hello

\$ mkdir tests/hello

and, in Makefile.in, we have to remove the line PLUGIN\_NO\_TEST:=yes.

File Makefile in

```
PLUGIN_HAS_MLI:=yes
include Makefile.plugin
```

Now we can add the following test hello.c in directory tests/hello.

File tests/hello/hello.c

```
/* run.config
    OPT: -hello
*/
/* A test of the plug-in hello does not require C code anyway. */
```

It is possible to test the new plug-in on this file with the command

\$ ./bin/toplevel.byte -hello tests/hello/hello.c

which should display

```
[preprocessing] running gcc -C -E -I. tests/hello.c
Hello Frama-C World!
```

The specific output of the plug-in hello is the last line.

It is also possible to use ptests to run tests automatically.

\$ ./bin/ptests.byte hello

The above command runs the Frama-C toplevel on each C file contained in the directory tests/hello. For each of them, it also uses directives following run.config given at the top of files. Here, for the test tests/hello/hello.c, the directive specifies that the toplevel has to be executed with the option -hello. Below is the output of this command.

```
% Dispatch finished, waiting for workers to complete
% System error while comparing. Maybe one of the files is missing...
tests/hello/result/hello.res.log or tests/hello/oracle/hello.res.oracle
% System error while comparing. Maybe one of the files is missing...
tests/hello/result/hello.err.log or tests/hello/oracle/hello.err.oracle
% Comparisons finished, waiting for diffs to complete
% Diffs finished. Summary:
Run = 1
Ok = 0 of 2
```

This result says that testing fails because it is not possible to compare the execution results with previously stored results (oracles). You have to execute:

\$ ./bin/ptests.byte -update hello

Thus each time one executes ptests.byte, differences with the saved oracles are displayed. Furthermore, you can easily check whether the changes in plug-in hello are compliant with all existing tests. For example, if we execute one more time:

```
$ ./bin/ptests.byte hello
% Diffs finished. Summary:
Run = 2
Ok = 2 of 2
```

This indicates that everything is alright.

Finally, you can also check if your changes break something else in the Frama-C kernel or in other plug-ins by executing ptests on all default tests with make tests.

**Note to SVN users** If you have write access to the SVN repository, you may commit your changes into the archive. Before that, you have to perform non-regression tests in order to ensure that your modifications do not break the archive.

So you must execute the following commands.

```
$ svn add ... # Do not forget new oracles
$ svn up
$ make tests
$ emacs<sup>5</sup> Changelog
$ svn commit -m "informative message"
```

If you created any new files, use the svn add command to add them into the archive. The svn up command updates your local directory with respect to the root repository. The make tests command performs the non-regression tests. Finally, *if and only if the regression tests do not expose any problem*, update the file Changelog according to your changes and commit them thanks with the svn commit command.

### 2.2.7 Copyright your Work

Target readers: developers with a SVN access.

If you want to redistribute plug-in hello, you have to choose a license policy for it (compatible with Frama-C). Section 4.18 provides details about how to proceed. Here, suppose we want to put the plug-in hello under the Lesser General Public License (LGPL) and CEA copyright, you simply have to edit the section "File headers: license policy" of Makefile.in with the following line:

Now executing:

\$ make headers

This adds an header on files of plug-in **hello** in order to indicate that they are under the desired license.

<sup>&</sup>lt;sup>5</sup>Or what other text editor you want to use.

# Chapter 3 Software Architecture

### Target readers: beginners.

In this chapter, we present the software architecture of Frama-C. First, Section 3.1 presents its general overview. Then, we focus on three different parts:

- Section 3.2 introduces the API of Cil [12] seen by Frama-C;
- Section 3.3 shows the organisation of the Frama-C kernel; and
- Section 3.4 explains the plug-in integration.

## **3.1** General Description

 $\mathsf{Frama-C}$  (Framework for Modular Analyses of C) is a software platform which helps the development of static analysis tools for C programs thanks to a plug-ins mechanism. This platform has to provide services in order to ease

- $\bullet$  analysis and source-to-source transformation of big-size C programs;
- addition of new plug-ins; and
- plug-ins collaboration.

In order to reach these goals, Frama-C is based on a software architecture with a specific design which is presented in this document. Figure 3.1 summarizes it. Mainly this architecture is separated in three different parts:

- Cil (C Intermediate Language) [12] extended with an implementation of the specification language ACSL (ANSI/ISO C Specification Language) [1]. That is the intermediate language upon which Frama-C is based. See Section 3.2 for details.
- The Frama-C kernel. That is a toolbox on top of Cil dedicated to static analyses. It provides data structures and operations which help the developer to deal with the Cil AST (Abstract Syntax Tree), as long as general services providing an uniform set of features to Frama-C. See Section 3.3 for details.
- The Frama-C plug-ins. That is analyses or source-to-source transformations which use the kernel and possibly others plug-ins through their API take in the Frama-C kernel. See Section 3.4 for details.

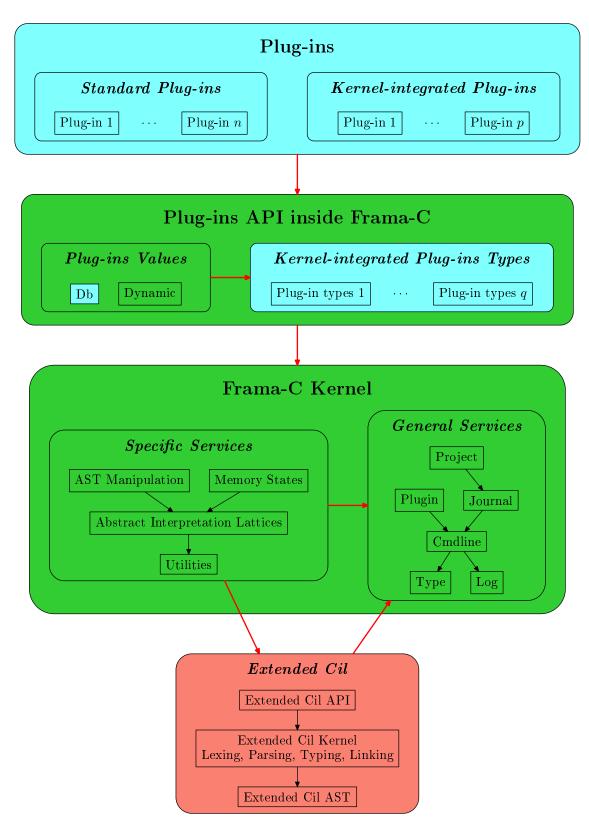

Figure 3.1: Architecture Design.

## 3.2 Cil: C Intermediate Language

Cil [12] is a high-level representation along with a set of tools that permit easy analysis and source-to-source transformation of C programs.

Frama-C uses Cil as a library which performs the main steps of the compilation of C programs (pre-processing, lexing, parsing, typing and linking) and outputs an abstract syntax tree (AST) ready for analysis. From the Frama-C developer's point of view, Cil is a toolbox usable through its API and providing:

- the AST description (module Cil\_types);
- useful AST operations (module Cil);
- some simple but useful miscellaneous datastructures and operations (mainly in module Cilutil); and
- some syntactic analysis like a (syntactic) call graph computation (module Callgraph) or generic forward/backward dataflow analysis (module Dataflow).

 $\ensuremath{\mathsf{Frama-C}}$  indeed extends Cil with ACSL (ANSI/ISO C Specification Language) [1], its specification language. The extended Cil API consequently provides types and operations in order to properly deal with annotated C programs.

Cil modules belong to directory (and subdirectories of) cil/src.

## 3.3 Kernel

On top of the extended Cil API, the Frama-C kernel groups together specific services providing in different modules which are described below.

- In addition to the Cil utilities, Frama-C provides useful operations (mainly in module Extlib) and datastructures (e.g. specialised version of association tables like Rangemap). These modules belong to directories src/lib and src/misc and they are not specific to analysis or transformation of C programs.
- Frama-C provides generic lattices useful for abstract interpretation (module Abstract\_interp) and some pre-instantiated arithmetic lattices (module Ival). The abstract interpretation toolbox is available in directory src/ai.
- Frama-C also provides different representations of C memory-states (module Locations) and data structures using them (e.g. association tables indexing by memory-states in modules Lmap and Lmap\_bitwise). The memory-state toolbox is available in directory src/memory\_state.
- Moreover, directory **src/kernel** provides a bunch of very helpful operations over the extended Cil AST. For example, module **Globals** provides operations dealing with global variables, functions and annotations while module **Visitor** provides inheritable classes in order to permit easy visiting, copying or in-place modification of the AST.

Besides, Frama-C also provides some very general-purpose services, used by all other modules (even the Frama-C version of Cil), which are shortly described below.

#### CHAPTER 3. SOFTWARE ARCHITECTURE

- Module Log provides an uniform way to display user messages in Frama-C.
- Module Cmdline parses the Frama-C command line.
- Module Plugin provides a high-level API on top of the two previous modules for the plug-in developer: a developer usually uses this modules and does not use modules Log nor Cmdline.
- Module Type is a library handling OCaml types as first-class values. Such values are required by journalization and registration of dynamic values. See section 4.8 for details.
- Module Journal handles how Frama-C journalizes its actions. See section ?? for details.
- In directory src/project, the Frama-C kernel embeds a library, called Project, which permits the consistency of results for multi-analysis of multi-ASTs in a dynamic setting. See section 4.11 for details.

## 3.4 Plug-ins

In Frama-C, plug-ins are analysis or source-to-source transformations. Each of them is an extension point of the Frama-C kernel. Frama-C allows plug-in collaborations: a plug-in p can use a list of plug-ins  $p_1, \ldots, p_n$  and conversely. Mutual dependences between plug-ins are even possible. If a plug-in is designed to be used by another plug-in, its API has to be registered, either in module Dynamic or in module Db. This last way is only available for kernel-integrated plug-ins.

More generally, the set of functionalities available for a standard plug-in and for a kernel-integrated plug-in are mostly the same. The differences between a standard plug-in and a kernel-integrated one are listed Figure 3.4.

Functionality	Standard plug-in	Kernel-integrated plug-in
dynamic linking	default	possible
static linking	$\mathbf{possible}$	default
API in Dynamic	$\mathbf{possible}$	$\operatorname{possible}$
API in Db	no	possible by modifying the kernel
add new abstract types	$\mathbf{possible}$	possible
add new concrete types	no	possible by modifying the kernel

Figure 3.2: Differences between standard plug-ins and kernel-integrated ones.

Both kinds of plug-ins may be either dynamically linked or statically linked within the Frama-C kernel. dynamic linking is the standard way for standard plug-ins while static linking is the standard way for kernel-integrated plug-ins.

Dynamic linking is only available in native mode if you have Objective Caml 3.11 or higher as long as a supported architecture. See the Objective Caml manual [9] for additional details.

Both kinds of plug-ins may register their API through module Dynamic, but the standard way for kernel-integrated plug-ins is the use of module Db. Kernel-integrated plug-ins may also declare any types inside the Frama-C kernel thanks to the so-called *'Kernel-integrated Plug-ins*.

Types'. Such types are usable by any plug-in, and even by some parts of the Frama-C kernel. However any plug-in may still register a new abstract type and use it through the function provided by the plug-in API. See Section 4.10 for details.

## Chapter 4

## Advanced Plug-in Development

This chapter details how to use services provided by Frama-C in order to be fully operational with the development of plug-ins. Each section describes technical points a developer should be aware of. Otherwise, one could find oneself in one or more of the following situations  $^{1}$  (from bad to worse):

- 1. reinventing the (Frama-C) wheel;
- being unable to do some specific things (e.g. saving results of your analysis on disk, see Section 4.11.3);
- 3. introducing bugs in your code;
- 4. introducing bugs in other plug-ins using your code;
- 5. breaking the kernel consistency and so potentially breaking all the Frama-C plug-ins (e.g. if you modify the AST without changing of project, see Section 4.11.2).

In this chapter, we suppose that the reader is able to write a minimal plug-in like hello described in chapter 2 and knows about the software architecture of Frama-C 3. Moreover plug-in development requires to use advanced features of OCaml (module system, classes and objects, *etc*). Static plug-in development requires some knowledge of autoconf and make. Each section summarizes its own prerequisites at its beginning (if any).

Note that the following subsections can be read in no particular order: their contents are indeed quite independent from one another even if the re are references from one chapter to another one. Pointers to reference manuals (Chapter 5) are also provided for readers who want full details about specific parts.

## 4.1 File Tree Overview

Target readers: beginners.

The Frama-C main directory is split in several sub-directories. Frama-C source code is mostly provided in directories cil and src. The first one contains the source code of Cil [12] extended

<sup>&</sup>lt;sup>1</sup>It is fortunately quite difficult (but not impossible) to fall into the worst situation by mistake if you are not a kernel developer.

with an ACSL [1] implementation. The second one is the core implementation of Frama-C. This last directory contains directories of the Frama-C kernel and directories of the provided Frama-C plug-in.

A pretty complete description of the Frama-C file tree is provided in Section 5.1.

## 4.2 Configure.in

Target readers: not for standard plug-ins developers.

Prerequisite: knowledge of autoconf and shell programming.

In this Section, we detail how to modify the file configure.in in order to configure plug-ins (Frama-C configuration has been introduced in Section 2.2.1 and 2.2.4).

First Section 4.2.1 introduces the general principle and organisation of configure.in. Then Section 4.2.2 explains how to configure a new simple plug-in without any dependency. Next we show how to exhibit dependencies with external libraries and tools (Section 4.2.3) and with other plug-ins (Section 4.2.4). Finally Section 4.2.5 presents the configuration of external libraries and tools needed by a new plug-in but not used anywhere else in Frama-C.

### 4.2.1 Principle

When you execute autoconf, file configure.in is used to generate script configure. Each Frama-C user executes this script which checks his system to determine the most appropriate configuration: at the end of this configuration (if it is successful), the script summarizes the status of each plug-in which can be:

- available (everything is fine with this plug-in);
- *partially available*: either an optional dependency of the plug-in is not fully available, or a mandatory dependency of the plug-in is only partially available; or
- *not available*: either the plug-in itself is not provided by default, or a mandatory dependency of the plug-in is not available.

The important notion in the above definitions is *dependency*. A dependency of a plug-in p is either an external library/tool or another Frama-C plug-in. It is either *mandatory* or *optional*. A mandatory dependency must be present in order to build p, whereas an optional dependency provides to p additional but not highly required features (especially p must be compilable without any optional dependency).

Hence, for the plug-in developer, the main role of configure.in is to define the optional and mandatory dependencies of each plug-in. Another standard job of configure.in is the addition of options --enable-p and --disable-p to configure for a plug-in p. These options respectively forces p to be available and disables p (its status is automatically "not available").

Indeed configure.in is organised in different sections specialised in different configuration checks. Each of them begins with a title delimited by comments and it is highlighted when configure is executed. These sections are described in Section 5.2. Now we focus on the modifications to perform in order to integrate a new plug-in in Frama-C.

## 4.2.2 Addition of a Simple Plug-in

In order to add a new plug-in, you have to add a new subsection for the new plug-in to Section *Plugin wished*. This action is usually very easy to perform by copying/pasting from another existing plug-in (*e.g.* occurrence) and by replacing the plug-in name (here occurrence) by the new plug-in name in the pasted part. In these sections, plug-ins are sorted according to a lexicographic ordering.

For instance, Section *Wished Plug-in* introduces a new sub-section for the plug-in occurrence in the following way.

The first argument is the plug-in name, the second one is the name of directory containing the source files of the plug-in, the third one is a help message for the -enable-occurence option of configure, the fourth one indicates if the plug-in is enabled by default and the last one indicates if the plug-in will be dynamically linked within the Frama-C kernel.

The macro check\_plugin sets the following variables: FORCE\_OCCURRENCE, REQUIRE\_OCCURRENCE, USE\_OCCURRENCE and ENABLE\_OCCURRENCE. DYNAMIC\_OCCURRENCE.

The first one indicates if the user explicitly requires the availability of occurrence via setting the option --enable-occurrence. The second and third ones are used by others plug-ins in order to handle their dependencies (see Section 4.2.4). The fourth ENABLE\_OCCURRENCE indicates the plug-in status (available, partially available or not available). At the end of these lines of code, it says if the plug-in should be compiled: if --enable-occurrence is set, then ENABLE\_OCCURRENCE is yes (plug-in available); if --disable-occurrence, then its value is no (plug-in not available). If no option is specified on the command line of configure, its value is set to the default one (according to \$default). Finally, DYNAMIC\_OCCURRENCE indicates whether the plug-in will be dynamically linked within the Frama-C kernel.

## 4.2.3 Addition of Library/Tool Dependencies

Three different variables are set for each external library and tool used in Frama-C which are

- HAS\_library
- REQUIRE\_*library*
- USE\_library

where library is the name of the considered library or tool (see Section 4.2.5 for explanations about their initialisations and their uses).

HAS\_*library* indicates whether the library is available on this platform (its value is yes) or not (its value is no). This last value is accessible in Makefile.in through the variable @HAS\_*library*@ (see Section 4.3). Actually we are not concerned by this value in this section.

**REQUIRE**\_*library* (resp. **USE**\_*library*) is a list of plug-in names (separated by spaces). It contains the plug-ins for which *library* is a mandatory (resp. an optional) dependency. So you have to extend these lists in order to add some library/tool dependencies for a new plug-in p.

**Recommendation 4.1** The best place to perform such extensions is just after the addition of p which sets the value of ENABLE\_p.

**Example 4.1** Plug-in gui requires Lablgtk2 [7]. So, just after its declaration, there are the following lines in configure.in.

```
if test "$ENABLE_GUI" == "yes"; then
    REQUIRE_LABLGTK=${REQUIRE_LABLGTK}" gui"
fi
```

These lines specify that Lablgtk2 must be available on the system if the user wants to compile gui.

### 4.2.4 Addition of Plug-in Dependencies

Adding a dependency with another plug-in is quite the same as adding a dependency with an external library or tool (see Section 4.2.3). For this purpose, configure.in uses variables REQUIRE\_plugin and USE\_plugin (in the same way that variables REQUIRE\_library and USE\_library: they are lists of plug-in names for which plugin is respectively a mandatory dependency or an optional dependency).

From the viewpoint of a plug-in developer, the difference between libraries and tools is that the best place to indicate such dependencies is not just after the addition of the plug-in: needed variables REQUIRE\_plugin and USE\_plugin could be undeclared at this point (in particular in the case of mutually dependent plug-ins). So dependency indications are postponed at the top of Section *Plug-in dependencies* of configure.in.

**Example 4.2** Plug-In value requires plug-in from and may use plug-in gui (for ValViewer [4]). So lists REQUIRE\_FROM and USE\_GUI contain value. Moreover, as many plugins require value, list REQUIRE\_VALUE is quite big. In particular, it contains plug-in from: both plug-ins value and from are indeed mutually dependent.

### 4.2.5 Configuration of New Libraries or Tools

Configuration of new libraries and configuration of new tools are similar. In this section, we therefore choose to focus on the configuration of new libraries.

Section 4.2.3 explains how to depend on some external library *library*. Nevertheless if *library* is not used by Frama-C anywhere else, you have to configure it.

First, you have to declare the three variables set by each library: HAS\_library, USE\_library and REQUIRE\_library. This is performed in Section Configuration of Plug-in Libraries of file configure.in. You should not assign values to these variables (just declare them).

Next, you have to export HAS\_library in Makefile.in through AC\_SUBST(HAS\_library) in Section Makefile Creation of configure.in.

Last but not least, you have to check that the library is available on the user system. A predefined macro called **configure\_library** helps the plug-in developer in this task<sup>2</sup>. **configure\_library** takes three arguments. The first one is the (uppercase) name of the library, the second one is a filename which is used by the script to check the availability of the library. In case there are multiple locations possible for the library, this argument can be

<sup>&</sup>lt;sup>2</sup>For tools, there is a macro configure\_tool which works in the same way as configure\_library.

#### 4.3 MAKEFILE IN

a list of filenames. In this case, the argument must be properly quoted (*i.e.* enclosed in a [, ] pair). Each name is checked in turn. The first one which corresponds to an existing file is selected and put in the variable SELECTED\_\$library\$. If no name in the list corresponds to an existing file, the library is considered to be unavailable. The last argument is a warning message to display if a configuration problem appear (usually because the library does not exist). Using these arguments, the script checks the availability of the library and, according to it, disables (resp. partially disables) the plug-ins requiring (resp. optionally using) it<sup>3</sup>.

When checking for Objective Caml libraries and object files, remember that they come in two flavors: bytecode and native code, which have distinct suffixes. Therefore, you should use the variables LIB\_SUFFIX (for libraries) and OBJ\_SUFFIX (for object files) to check the presence of a given file. These variables are initialized at the beginning of the configure script depending on the availability of a native-code compiler on the current installation.

**Example 4.3** The library Lablgtksourceview (used to have a better rendering of C sources in the GUI) can be found either as part of Lablgtk2 or as an independent library. This is checked through the following command:

```
configure_library(
  [GTKSOURCEVIEW],
  [$0CAMLLIB/lablgtk2/lablgtksourceview.$LIB_SUFFIX,
  $0CAMLLIB/lablgtksourceview/lablgtksourceview.$LIB_SUFFIX],
  [lablgtksourceview not found])
```

Moreover, we want to distinguish the two cases, as the independent library denotes a legacy version of Lablgtksourceview, which has been merged with Lablgtk2. This is done by pattern-matching on the variable SELECTED\_GTKSOURCEVIEW as shown below:

```
case $SELECTED_GTKSOURCEVIEW in
$OCAMLLIB/lablgtksourceview/lablgtksourceview.$LIB_SUFFIX)
HAS_LEGACY_GTKSOURCEVIEW=yes
;;
esac
```

## 4.3 Makefile.in

Target readers: not for standard plug-in developers.

**Prerequisite:** knowledge of make.

In this section, we detail the use of Makefile.in dedicated to Frama-C compilation. This file is split in several sections which are described in Section 5.3.2. By default, executing make only displays an overview of commands. For example, here is the output of the compilation of source file src/kernel/db.cmo.

```
$ make src/kernel/db.cmo
Ocamlc src/kernel/db.cmo
```

If you wish the exact command line, you have to set variable VERBOSEMAKE to yes like below.

```
$ make VERBOSEMAKE=yes src/kernel/db.cmo
ocamlc.opt -c -w Ael -warn-error A -dtypes -I src/misc -I src/ai
-I src/memory_state -I src/toplevel -I src/slicing_types -I src/pdg_types
-I src/kernel -I src/logic -I src/cxx_types -I src/gui -I lib/plugins
-I lib -I src/lib -I src/project -I src/buckx -I external -I src/project
-I src/buckx -I cil/src -I cil/src/ext -I cil/src/frontc -I cil/src/logic
-I cil/ocamlutil -g src/kernel/db.ml
```

<sup>&</sup>lt;sup>3</sup>As plug-in dependencies are checked after this check, plug-ins are not recursively disabled here.

In order to integrate a new plug-in, you have to extend section "Plug-ins". For this purpose, you have to include Makefile.plugin for each new plug-in (hence there are as many lines include Makefile.plugin as plug-ins). Makefile.plugin is a generic makefile dedicated to plug-in compilation. Before its inclusion, a plug-in developer can set some variables in order to customize its behavior. These variables are fully described in Section 5.3.3.

These variables must not be used anywhere else in Makefile.in. Moreover, for setting them, you must use := and not  $=^{4}$ .

**Example 4.4** For compiling the plug-in Value, the following lines are added into Makefile.in.

As said above, you cannot use the parameters of Makefile.plugin anywhere in Makefile.in. You can yet use some plugin-in specific variables once Makefile.plugin has been included. These variables are detailed in Section 5.3.3.

One other variable has to be modified by a plug-in developer if he uses files which do not belong to the plug-in directory (that is if variable PLUGIN\_TYPES\_CMO is set). This variable is UNPACKED\_DIRS and corresponds to the list of non plug-in directories containing source files.

A plug-in developer should not modify any other part of Makefile.in or Makefile.plugin.

## 4.4 Plug-in Specific Makefile

**Prerequisite:** knowledge of make.

In this section, we detail how to add a Makefile to a plug-in. Section 4.4.1 introduces how to write a Makefile for its own plug-in thanks to Makefile.dynamic while Section 4.4.2 explains how to integrate it in Makefile.in.

### 4.4.1 Using Makefile.dynamic

In this section, we detail how to write a Makefile for its own plug-in. Even if it is still possible to write such a Makefile from scratch, Frama-C provides a generic Makefile, called Makefile.dynamic, which helps the plug-in developer to write it. This file is installed in the Frama-C share directory. So for writting your plug-in specific Makefile, you have to:

 $<sup>^{4}</sup>$ Using := only sets the variable value from the affectation point (as usual in most programming langages) whereas using = would redefine the variable value for each of its occurrences in the makefile (see Section 6.2 "The Two Flavors of Variables" of the GNU Make Manual [6]).

- 1. set some variables for customizing your plug-in;
- 2. include Makefile.dynamic.

**Example 4.5** A minimal Makefile is shown below. That is the Makefile of the plug-in Hello World presented in the tutorial (see Section 2.1.2). Each variable set in this example has to be set by any plug-in.

FRAMAC\_SHARE must be set to the Frama-C share directory while FRAMAC\_LIB must be set to the Frama-C lib directory. PLUGIN\_NAME is the capitalized name of your plug-in while PLUGIN\_CMO is the list of the files .cmo generated from your OCaml sources.

For running your specific Makefile, you must have properly installed Frama-C before.

Eventually it may be required to do make depend before running make.

Which variable can be set and how they are useful is explained Section 5.3.3. Furthermore, Section 5.3.4 explains the specific features of Makefile.dynamic.

#### 4.4.2 Calling a Plug-in Specific Makefile from the Frama-C Makefile

Target readers: kernel-integrated plug-in developers using the SVN repository of Frama-C.

Even if you are writting a kernel-integrated plug-in, it is useful to have your plug-in specific Makefile. For instance, it allows you to easily release your plug-in independently of Frama-C. However, if your version of Frama-C is changing frequently, it is useful to compile together Frama-C and your plug-in without installing Frama-C each time. To reach this goal, you have to mix the integration in Makefile.in described in Section 4.3 and the solution presented in this section: in the section "Plug-ins" of Makefile.in you just have to set few variables before including your plug-in specific Makefile

**Example 4.6** For compiling the plug-in Ltl\_to\_acsl, the following lines are added into Makefile.in.

```
PLUGIN_ENABLE := @ENABLE_LTL_TO_ACSL@
PLUGIN_DIR := src/ltl_to_acsl
PLUGIN_DYNAMIC := @DYNAMIC_LTL_TO_ACSL@
DISTRIB_FILES += $(PLUGIN_DIR)/Makefile
include $(PLUGIN_DIR)/Makefile
```

## 4.5 Testing

In this section, we present ptests, a tool provided by Frama-C in order to perform non-regression and unit tests.

ptests runs the Frama-C toplevel on each specified test (which are usually C files). Specific directives can be used for each test. Each result of the execution is compared from the previously saved result (called the *oracle*). Test is successful if and only if there is no difference. Actually the number of results is twice that the number of tests because standard and error outputs are compared separately.

First Section 4.5.1 shows how to use **ptests**. Next Section 4.5.2 explains how to configure tests through directives. Last Section 4.5.3 describes how to set up various testing goals for the same test base.

#### 4.5.1 Using ptests

The simplest way of using ptests is through make tests which is roughly equivalent to

```
$ time ./bin/ptests.byte
```

This command runs all the tests belonging to a sub-directory of directory tests. ptests also accepts specific *test suites* in arguments. A test suite is either a name of a sub-directory in directory tests or a filename (with its complete path).

**Example 4.7** If you want to test plug-in sparecode and specific test tests/pdg/variadic.c, just run

\$ ./bin/ptests.byte sparecode tests/pdg/variadic.c

which should display (if there are 7 tests in directory tests/sparecode)

```
% Dispatch finished, waiting for workers to complete
% Comparisons finished, waiting for diffs to complete
% Diffs finished. Summary:
Run = 8
Ok = 16 of 16
```

ptests accepts different options which are used in order to customize one test sequence. These options are detailed in Section 5.4.

**Example 4.8** If code of plug-in plug-in has changed, a typical sequence of tests is the following one.

\$ ./bin/ptests.byte plug-in
\$ ./bin/ptests.byte -update plug-in
\$ make tests

So we first run the tests suite corresponding to plug-in in order to display what tests have been modified by the changes. After checking the displayed differences, we validate the changes by updating the oracles. Finally we run all the test suites in order to ensure that the changes do not break anything else in Frama-C.

#### 4.5.2 Configuration

In order to exactly perform the test that you wish, some directives can be set in three different places. We indicate first these places and next the possible directives.

The places are:

- inside file tests/test\_config;
- inside file tests/subdir/test\_config (for each sub-directory subdir of tests); or
- inside each test file, in a special comment of the form

```
/* run.config
... directives ...
*/
```

In each of the above case, the configuration is done by a list of directives. Each directive has to be on one line and to have the form

```
CONFIG_OPTION: value
```

There is exactly one directive by line. The different directives (*i.e.* possibilities for  $CONFIG_OPTION$ ) are detailed in Section 5.4.

Example 4.9 Test tests/sparecode/calls.c declares the following directives.

```
/* run.config
    OPT: -sparecode-analysis
    OPT: -slicing-level 2 -slice-return main -slice-print
*/
```

They say that we want to test sparecode and slicing analyses on this file. Thus running the following instruction executes two test cases.

```
$ ./bin/ptests.byte tests/sparecode/calls.c
% Dispatch finished, waiting for workers to complete
% Comparisons finished, waiting for diffs to complete
% Diffs finished. Summary:
Run = 2
Ok = 4 of 4
```

#### 4.5.3 Alternative Testing

You may want to set up different testing goals for the same test base. Common cases include:

- checking the result of an analysis with or without an option;
- checking a preliminary result of an analysis, in particular if the complete analysis is costly;
- checking separately different results of an analysis.

This is possible with option -config of ptests, which takes as argument the name of a special test configuration, as in

```
$ ./bin/ptests.byte -config <special_name> plug-in
```

Then, the directives for this test can be found:

- inside file tests/test\_config\_<special\_name>;
- inside file tests/subdir/test\_config\_<special\_name> (for each sub-directory subdir of tests); or
- inside each test file, in a special comment of the form

```
/* run.config_<special_name>
    ... directives ...
*/
```

All operations for this test configuration should take option -config in argument, as in

```
$ ./bin/ptests.byte -update -config <special_name> plug-in
```

In addition, tests relying on custom dynamically-linked plug-ins must either be always executed in bytecode or provide an alternative configuration named no\_native\_dynlink which performs the test in bytecode, in order for the test to be launched on architectures which do not support native dynlink. If those tests have other special configurations, they must similarly provide for each them a corresponding <special\_name>\_no\_native\_dynlink.

## 4.6 Plug-in General Services

Module Plugin provides an access to some general services available for all plug-ins. The goal of this module is twofold. First, it helps the developper to use some features of Frama-C. Second, it allows to provide to the end-user a common set of features for all plug-ins. To access to these services, you have to apply the functor Plugin.Register.

Each plug-in must apply this functor exactly once.

**Example 4.10** Here is how the plug-in From applies the functor Plugin.Register for its own use.

Applying this functor mainly provides two different services. First it gives access to functions for printing messages in a Frama-C-compliant way (see Section 4.7). Second it allows to define plug-in specific parameters available as option on the Frama-C command line for the end-user (see Section 4.12).

## 4.7 Writing messages

**TODO:** not written yet

## 4.10 Plug-in Registration and Access

In this section, we present how to register plug-ins and how to access them. Actually there are two different ways to register plug-ins depending on whether they are kernel-integrated or not (cf Section 3.4).

Section 4.10.1 indicates how to register and access a *kernel-integrated* plug-in while Section 4.10.2 details how to register and access a *standard* plug-in.

#### 4.10.1 Kernel-integrated Registration and Access

Target readers: kernel-integrated plug-ins developers.

**Prerequisite:** Accepting to modify the Frama-C kernel. Otherwise, you can still register your plug-in as any standard plug-in (see Section 4.10.2 for details).

A database, called Db (in directory src/kernel), groups together the API of all kernelintegrated plug-ins. So it permits easy plug-in collaborations. Each kernel-integrated plug-in is only visible through Db. For example, if a plug-in A wants to know the results of another plug-in B, it uses the part of Db corresponding to B. A consequence of this design is that each plug-in has to register in Db by setting a function pointer to the right value in order to be usable from others plug-ins.

Example 4.11 Plug-in Impact registers function compute\_pragmas in the following way.

File src/impact/register.ml

|et compute\_pragmas () = ... |et () = Db.Impact.compute pragmas ← compute pragmas

So each developer who wants to use this function calls it by pointer dereferencing like this.

let () = !Db.Impact.compute\_pragmas ()

If a kernel-integrated plug-in has to export some datatypes usable by other plug-ins, such datatypes have to be visible from module Db. Thus they cannot be declared in the plug-in implementation itself like any other plug-in declaration because postponed type declarations are not possible in Objective Caml.

Such datatypes are called *plug-in types*. The solution is to put these plug-ins types in some files linked before **Db**; hence you have to put them in another directory than the plug-in directory. The best way is to create a directory dedicated to types even if it is possible to put a single file in another directory or to put a single type in an existing file (like **src/kernel/db\_types.mli**).

**Recommendation 4.2** The suggested name for this directory is p\_types for a plug-in p.

If you add such a directory, you also have to modify Makefile.in by extending variable UNPACKED\_DIRS (see Section 5.3.3).

**Example 4.12** Suppose you are writing a plug-in plug-in which exports a specific type t corresponding to the result of the plug-in analysis. The standard way to proceed is the following.

```
File src/plugin_types/plugin_types.mli
```

File src/kernel/db.mli

```
module Plugin : sig
va| run_and_get: (unit → Plugin_types.t) ref
   (** Run plugin analysis (if it was never launched before).
        @return result of the analysis. *)
end
```

File Makefile.in

```
UNPACKED_DIRS= ... plugin_types 
# Extend this variable with the new directory
```

This design choice has a side effect : it reveals exported types. You can always hide them using a module to encapsulate the types (and provide corresponding getters and setters to access them).

At this point, part of the plug-in code is outside the plug-in implementation. This code should be linked before  $Db^{5}$ .

To this effect, the files containing the exterior plug-in code must be added to the Makefile variable PLUGIN\_TYPES\_CMO (see Section 5.3.3).

#### 4.10.2 Dynamic Registration and Access

Target readers: standard plug-ins developers.

Registration of kernel-integrated plug-ins requires to modify module Db which belongs to the Frama-C kernel. Such a modification is not possible for standard plug-ins which are fully independent of Frama-C. Consequently, the Frama-C kernel provides another way for registering a plug-in through the module Dynamic.

Shortly, you have to use the function Dynamic.register in order to register a value from a dynamic plug-in and you have to use function Dynamic.get in order to apply a function previously registered with Dynamic.register.

**Registering a value** The signature of Dynamic.register is as follows.

| va| register: string  $\rightarrow$  'a Type.t  $\rightarrow$  'a  $\rightarrow$  unit

 $<sup>{}^{5}\</sup>mathrm{A}$  direct consequence is that you cannot use the whole Frama-C functionalities inside this code, such as module Db.

The first argument is a binding name of the registered OCaml value. It must not be used for value registration anywhere else in the Frama-C world. It is required for another plug-in in order to access to this value (see next paragraph). The second argument is the so-called *type value* of the registered value, *i.e.* an OCaml value representing its type (see Section 4.8 for additional details). It is required for safety reasons when accessing to the registered value (see next paragraph). Predefined type values exist in modules Type (for usual OCaml types like int) and Kernel\_type (for usual Frama-C types like Cil\_types.varinfo). The third argument is the value itself.

**Example 4.13** Here is how the function run of the plug-in hello of the tutorial is registered. The type of this function is unit  $\rightarrow$  unit.

let run () = ...
let () = Dynamic.register "Hello.run" (Type.func Type.unit Type.unit) run

If the string "Hello.run" is already used to register a dynamic value, then the exception Type.AlreadyExists is raised during plug-in initialisation (see Section 4.13).

The function call Type.func Type.unit Type.unit returns the type value of unit  $\rightarrow$  unit. Note that, because of the type of Dynamic.register and the types of its arguments, the OCaml type checker complains if the third argument (here the value run) has not the type unit  $\rightarrow$  unit.

**Calling a previously-registered function** The signature of function Dynamic.get is as follows.

| val get: string  $\rightarrow$  'a Type.t  $\rightarrow$  'a

The first argument must be the binding name of the OCaml value registered with Dynamic.register. The second argument is the type value of this registered value. It is required for safety reasons. The third argument is the value itself.

Example 4.14 Here is how the previously registered function run of Hello may be applied.

The given string and the given type value have to be the same than the ones used when registering the function. Otherwise, the exceptions Type.Unbound\_value and Type.StringTbl.Incompatible\_Type are respectively raised. Furthermore, because of the type of Dynamic.get and the types of its arguments, the OCaml type checker complains either if the third argument (here ()) is not of type unit or if the returned value (here () also) is not of type unit.

## 4.11 Project Management System

**Prerequisite:** knowledge of OCaml module system and labels.

In Frama-C, a key notion detailed in this section is the one of *project*. Technical details may also be found in a related article [13]. Section 4.11.1 first introduces the general principle of project. Then Section 4.11.2 explains how to simply use them. Section 4.11.3 introduces the so-called *internal states* for which registration is detailed in Sections 4.11.4, 4.11.5 and 4.11.6. Section 4.11.4 is dedicated to so-called *datatypes*. Section 4.11.5 is dedicated to the internal states themselves. Section 4.11.6 is dedicated to low-level registration. Finally Section 4.11.7 shows how to handle projects and internal states in a clever and proper way.

#### 4.11.1 Overview and Key Notions

In Frama-C, many (mostly global) data are attached to an AST. For example, there are the AST itself, options of the command line (see Section 4.12) and tables containing results of analyses (Frama-C extensively uses memoization [10, 11] in order to avoid re-computating analyses). The set of all these data is called a *project*. It is the only value savable on the disk and restorable by loading.

Several ASTs can exist at the same time in Frama-C and thus several projects as well; there is one AST per project. Besides each data has one value per AST: thus there are as many values for each data as projects/ASTs.

The set of all the projects stands for *the internal state of* Frama-C : it consists of all the ASTs defined in Frama-C and, for each of them, the corresponding values of all the attached data.

A related notion is *internal state* of a data d. That is the different values of d in projects: for each data, the cardinal of this set is equal to the cardinal of the internal state of Frama-C (*i.e.* the number of existing projects).

These notions are summarized in Figure 4.1. One row contains the value of each data for a specific project and one line represents an internal state of a specific data.

Projects Internal states	Project $p_1$	 Project $p_n$
AST a	value of $a$ in $p_1$	 value of $a$ in $p_n$
data $d_1$	value of $d_1$ in $p_1$	 value of $d_1$ in $p_n$
data $d_m$	value of $d_m$ in $p_1$	 value of $d_m$ in $p_n$

Figure 4.1: Representation of the Frama-C Internal State.

#### 4.11.2 Using Projects

Actually Frama-C maintains a current project (Project.current ()) and a current AST (Ast.get ()) which all operations are automatically performed on. But sometimes plug-in developers have to explicitly use them, for example when the AST is modified (usually through the use of a copy visitor, see Section 4.15) or replaced (*e.g.* if a new one is loaded from disk).

An AST must never be modified inside a project. If such an operation is required, you must create a new project with a new AST, usually by using File.init\_project\_from\_cil\_file or File.init\_project\_from\_visitor.

Operations over projects are grouped together in module **Project**. A project has type **Project.t**. Function **Project.set\_current** sets the current project on which all operations are implicitly performed on the new current project.

**Example 4.15** Suppose that you saved the current project into file foo.sav in a previous Frama-C session<sup>6</sup> thanks to the following instruction.

Project.save "foo.sav"

<sup>&</sup>lt;sup>6</sup>A session is one execution of Frama-C (through frama-c or frama-c-gui).

In a new Frama-C session, executing the following lines of code (assuming the value analysis has never been computed previously)

```
let print_computed () = Format.printf "%b@." (Db.Value.is_computed ()) in
print_computed (); (* false *)
let old = Project.current () in
try
  let foo = Project.load ~name:"foo" "foo.sav" in
  Project.set_current foo;
  !Db.Value.compute ();
  print_computed (); (* true *)
  Project.set_current old;
  print_computed () (* false *)
with Project.IOError _→
  exit 1
```

displays

false true false

This example shows that the value analysis has been computed only in project foo and not in project old.

An alternative to the use of **Project.set\_current** is the use of **Project.on** which applies an operation on a given project without changing the current project (*i.e.* locally switch the current project in order to apply the given operation and, after, restore the initial context).

**Example 4.16** The following code is equivalent to the one given in Example 4.15.

```
let print_computed () = Format.printf "%b@." (Db.Value.is_computed ()) in
print_computed (); (* false *)
try
  let foo = Project.load ~name:"foo" "foo.sav" in
  Project.on foo
    (fun () → !Db.Value.compute (); print_computed () (* true *)) ();
  print_computed () (* false *)
with Project.IOError _→
  exit 1
```

It displays

false true false

#### 4.11.3 Internal State: Principle

If a data should be part of the internal state of Frama-C, you must register it as an internal state (also called a *computation* because it is often related to memoization).

Here we first explain what are the functionalities of each internal state and then we present the general principle of registration.

#### Internal State Functionalities

Whenever you want to attach a data (e.g. a table containing results of an analysis) to an AST, you have to register it as an internal state. The main functionalities provide to each internal state are the following.

- It is automatically updated whenever the current project changes: so your data is always consistent with the current project.
- It is part of the information saved on disk for restoration in a later session.
- It may be part of a *selection* which is, roughly speaking, a set of internal states. Which such a selection, you can control which internal states project operations are applied on (see Section 4.11.7). For example, it is possible to clear all the internal states which depend of the value analysis.
- It is possible to ensure inter-analysis consistency by setting internal state dependencies. For example, if the entry point of the analysed program is changed (using Globals.set\_entry\_point), all the results of analyses depending of it (like the value analysis) are automatically reset. If such a reset was not performed, the results of the value analysis would be not consistent with the current entry point.

**Example 4.17** Suppose that the value analysis has previously been computed.

```
Format.printf "%b@." (!Db.Value.is_computed ()); (* true *)
Globals.set_entry_points "f" true;
Format.printf "%b@." (!Db.Value.is_computed ()); (* false *)
```

- As the value analysis has been reset by setting the entry point, the above code outputs
  - true false

#### Internal State Registration: Overview

For registering a new internal state, functor Project.Computation.Register is provided. Actually it is quite a low-level functor. Higher-level functors are provided to the developer by modules Computation and Kernel\_computation that register internal states in a simpler way. They internally apply the low-level functor in a proper way. Module Computation provides internal state builders for standard OCaml datastructures like hashtables whereas Kernel\_computation does the same for standard Frama-C datastructures (like hashtables indexed by AST statements)<sup>7</sup>.

Registering a new internal state must be performed before parsing command line option. For this purpose, you can register your function through Cmdline.run\_after\_extending\_stage (see Section 4.13).

Section 4.11.5 details how to register a new computation.

The registration of a data of type  $\tau$  requires to register the type  $\tau$  itself as a *datatype* using functor Project.Datatype.Register. A datatype is a type that is aware of projects. Similarly to computations, module Datatype (resp. Kernel\_datatype) provides pre-defined datatypes and datatypes-builder for elaborated types<sup>8</sup>. Section 4.11.4 details how to register a new datatype.

**Example 4.18** If you have to register a reference to a boolean initialized to false as an internal state, you have to write the following code.

<sup>&</sup>lt;sup>7</sup>These datastructures are only mutable datastructures (like hashtables, arrays and references) because global states are always mutable.

<sup>&</sup>lt;sup>8</sup>On the contrary to computations, these types are either mutable or persistent because the registration of a type may require the registration of its subtypes (in the sense of syntactically contained in).

```
module My_Bool_Ref =
   Computation.Ref
   (struct include Datatype.Bool |et default = false end)
      (struct |et dependencies = [] |et name = "My_Bool_Ref" end)
```

#### 4.11.4 Registering a New Datatype

In order to register a new datatype, you have to apply functor **Project.Datatype.Register** which is a quite low-level functor. In most cases, a direct application of this functor is actually not required because some higher-level and easier-to-use functor does it for you. We explain here the three different possible situations.

**Simple registration** If the datatype to register is not hash-consed<sup>9</sup> or does not contain hash-consed ones (*i.e.* it is not itself hash-consed or composed of Cil\_types.fundec, or any Frama-C abstract interpretation type), the easiest way of registering a new datatype d is to apply one of functors Persistent or Imperative of module Project.Datatype, depending on the nature of d (whether it is persistent). The only difference between both functors is that you have to provide a copy function for imperative (*i.e.* mutable) datatypes. This copy function is only used by Project.copy.

Example 4.19 For registering a type t containing an immutable field a, just do

```
type a = { a : int }
Project.Datatype.Persistent(struct type t = a |et name = "a" end)
```

If the field a is mutable, just write

```
type a = { mutable a : int }
Project.Datatype.Imperative
(struct
    type t = a
    let copy x = { a = x.a }
    let name = "a"
end)
```

Using predefined datatypes or datatype builders For most useful types, the corresponding datatypes are already provided in modules Datatype (e.g. Datatype.Int for type int) and Kernel\_datatype (e.g. Kernel\_datatype.Stmt for type Cil\_types.stmt). Moreover both modules provides a bunch of functors which help to build complex datatypes when Project.Datatype.Persistent and Project.Datatype.Imperative cannot be used. Interfaces of modules Datatype and Kernel\_datatype provided all the available modules.

**Example 4.20** For registering the type of an hashtable associating varinfo to list of kernel functions, it is not possible to apply functor Project.Datatype.Imperative because a kernel function is composed of Cil\_types.fundec. But it is still easy to perform the registration thanks to predefined functors:

Kernel\_datatype.VarinfoHashtbl (Datatype.List(Kernel\_datatype.KernelFunction))

<sup>&</sup>lt;sup>9</sup>Hash-consing is a programming technique saving memory blocks and speeds up operations on datastructures when sharing is maximal [5, 8, 2, 3].

**Direct use of the low-level functor** In some cases (*e.g.* registering a new variant type composed of a kernel function), applying functor **Project.Datatype.Register** is required. As input, one has to provide:

- The type itself.
- How to copy and to rehash it (usually just rebuild the structure by applying the right copy and rehash functions on subterms).
- A name for the datatype.

**Example 4.21** The type of postdominators is the following variant.

| type postdominator = Value of Cilutil.StmtSet.t | Top

The corresponding registed datatype used to store results of the postdominator computation is the following (see file src/postdominators/compute.ml).

```
Project.Datatype.Register
(struct
   type t = postdominator
   let map f = function
        | Top → Top
        | Value set → Value (f set)
        let copy = map Kernel_datatype.StmtSet.copy
        let rehash = map Kernel_datatype.StmtSet.rehash
        let name = "postdominator"
end)
```

#### 4.11.5 Registering a New Internal State

Here we explain how to register and use an internal state in Frama-C. Registration through the use of low-level functor Project.Computation.Register is postponed in Section 4.11.6 because it is more tricky and rarely useful.

In most non-Frama-C applications, a state is a (usually global) mutable value. One can use it in order to store results of the analysis. For example, inside Frama-C, the following piece of code would use value state in order to memoize some information attached to statements.

```
open Cilutil
type info = Kernel_function.t * Cil_types.varinfo
let state : info StmtHashtbl.t = StmtHashtbl.create 97
let compute_info = ...
let memoize s =
   try StmtHashtbl.find state s
   with Not_found → StmtHashtbl.add state s (compute_info s)
let run () = ... !Db.Value.compute (); ... memoize some_stmt ...
```

However, if one puts this code inside Frama-C, it does not work because this state is not registered as a Frama-C internal state. A direct consequence is that it is not saved on the disk. For this purpose, one has to transform the above code into the following one.

```
module State =
   Kernel_computation.StmtHashtbl
   (Datatype.Couple
        (Kernel_datatype.KernelFunction)(Kernel_datatype.Varinfo))
   (struct
        let size = 97
        let name = "state"
        let dependencies = [Db.Value.self ]
        end)
   let compute_info = ...
   let memoize = State.memo compute_info
   let run () = ... !Db.Value.compute (); ... memoize some stmt ...
```

#### 4.11. PROJECT MANAGEMENT SYSTEM

A quick look on this code shows that the declaration of the state itself is much more complicated (it uses a functor application) but the use of state is simpler. Actually what has changed?

- 1. To declare a new internal state, apply one of the predefined functors in modules Computation or Kernel\_computation (see interfaces of these modules for the list of available modules). Here we use StmtHashtbl which provides an hashtable indexed by statements. The type of values associated to statements is a couple of Kernel\_function.t and Cil\_types.varinfo. The first argument of the functor is the datatype corresponding to this type (see Section 4.11.4). The second argument provides some additional information: the initial size of the hashtable (an integer similar to the argument of Hashtbl.create), a name for the resulting state and its dependencies. This list of dependencies is built upon values self which are provided by the application of the low-level functor Project.Computation.Register. This value is called the *kind* of the internal state (also called *state kind* and can be used for this purpose. Roughly speaking, it represents the internal state itself.
- 2. From outside, a state actually hides its internal representation in order to ensure some invariants: operations on states implementing hashtable does not take an hashtable in argument because they implicitly use the hidden hashtable. In our example, a predefined memo function is used in order to memoize the computation of compute\_info. This memoization function implicitly operates on the hashtable hidden in the internal representation of State.

**Postponed dependencies** A plug-in p may want to export its state kind (in the previous example, that is value **State.self**). This exportation offers the possibility to other plug-ins to depend on this state. It is a bit tricky because the state kind has to be accessible through Db.

There is two ways to achieve such a goal. First, the internal state has to be compiled before **Db**: usually the internal state has to be somewhere in directory  $p_{types}$  (see Section 4.10.1). Actually it is quite difficult because the computation of the internal state may be complex and so should not be in  $p_{types}$ .

The second way is to put a delayed reference to self (*i.e.* the state kind) in Db thanks to Project.Computation.dummy which provides a dummy kind. This reference is going to be initialised at the plug-in initialisation time (see Section 4.13). Now if another plug-in has an internal state which depends on !Db.My\_plugin.self, it cannot put the dependence when the functor creating the state is applied because the order of plug-in initialisation is not specified (see Section 4.13 for more details about initialisation steps). So you have to postpone the addition of this dependency; usually by using the function Cmdline.run\_after\_extending\_stage (see Section 4.13).

Example 4.22 Plug-in from postpones its internal state in the following way.

```
File src/kernel/db.mli
module From = struct
...
val self: Project.Computation.t ref
end
```

File src/kernel/db.ml

```
module From = struct
...
val self = ref Project.Computation.dummy (* postponed *)
end
```

File src/from/register.ml

Plug-in pdg uses from for computing its own internal state. So it declares this dependency as follow.

```
File src/pdg/register.ml
```

For standard plug-ins, it is possible to register state kinds in the same way that any other value through Dynamic.register (see Section 4.10.2).

#### 4.11.6 Direct Use of Low-level Functor Project.Computation.Register

Functor Project.Computation.Register is the only functor which really registers an internal state. All the others internally use it. In some cases (*e.g.* if you define your own mutable record used as a state), you have to use it. Actually, in the Frama-C kernel, there is no direct use of this functor.

This functor takes three arguments. The first and the third ones respectively correspond to the datatype and to information (name and dependencies) of the internal states: they are similar to the corresponding arguments of the high-level functors (see Section 4.11.5).

The second argument explains how to handle the *local version* of the value of the internal state (under registration). Indeed here is the key point: from the outside, only this local version is used for efficiency purpose. It would work if projects do not exist. Each project knows a *global version*: the set of these global versions is the so-called *internal states*. The project management system *automatically* switches the local version when the current project changes in order to conserve a physical equality between local version and current global version. So, for this purpose, the second argument provides a type t (type of values of the state) and four functions create (creation of a new fresh state), clear (cleaning a state), get (getting a state) and set (setting a state).

The following invariants must hold:<sup>10</sup>

create () returns a fresh value (4.1	1
--------------------------------------	---

```
\forall p \text{ of type t, create ()} = (clear p; set p; get ()) (4.2)
```

```
\forall p \text{ of type t, copy } p \text{ returns a fresh value} (4.3)
```

```
\forall p1, p2 \text{ of type tsuch that } p1 != p2, (set p1; get ()) != p2 (4.4)
```

Invariant 4.1 ensures that there is no sharing with any fresh value of a same internal state: so each new project has got its own fresh internal state. Invariant 4.2 ensures that cleaning a state resets it to its initial value. Invariant 4.3 ensures that there is no sharing with any copy. Invariant 4.4 is a local independence criteria which ensures that modifying a local version does not affect any other version (different of the global current one) by side-effect.

**Example 4.23** To illustrate this, we show how functor Computation. Ref (registering a state corresponding to a reference) is implemented.

```
module Ref(Data:REF_INPUT)(Info:Signature.NAME_DPDS) = struct
type data = Data.t
let create () = ref Data.default
let state = ref (create ())
```

Here we use an additional reference: our local version is a reference on the right state. We can use it in order to safely and easily implement get and set required by the registration.

```
include Project.Computation.Register
(Datatype.Ref(Data))
(struct
  type t = data ref (* we register a reference on the given type *)
  let create = create
  let clear tbl = tbl ← Data.default
  let get () = !state
  let set x = state ← x
end)
(Info)
```

For users of this module, we export "standard" operations which hide the local indirection required by the project management system.

As you can see, the above implementation is error prone; in particular it uses a double indirection (reference of reference). So be happy that higher-level functors like Computation.Ref are provided which hide you such implementations.

## 4.11.7 Selections

Most operations working on a single project (*e.g.* Project.clear or Project.on) have two optional parameters only and except of type Project.Selection.t. These parameters allow to specify which internal states the operation applies on:

• If only is specified, the operation is *only* applied on the selected internal states.

 $<sup>^{10}</sup>$ As usual in OCaml, = stands for *structural* equality while == (resp. !=) stands for *physical* equality (resp. disequality).

- If except is specified, the operation is applied on all internal states, *except* the selected ones.
- If both only and except are specified, the operation *only* applied on the only internal states, *except* the except ones.

A *selection* is roughly speaking a set of internal states. Moreover it handles states dependencies (that is the specificity of selections).

**Example 4.24** The following statement clears all the results of the value analysis and all its dependencies in the current project.

```
Project.clear
~only:
(Project.Selection.singleton Db.Value.self Kind.Select_Dependencies)
()
```

The argument Kind.Select\_Dependencies says that we also want to clear all the states which depend on the value analysis.

Use selections carefully: if you apply a function f on a selection s and if f handles a state which does not belong to s, then the Frama-C state becomes lost and inconsistent.

**Example 4.25** The following statement applies a function f in the project p (which is not the current one). For efficiency purpose, we restrict the considered states to the command line options (see Section 4.12).

Project.on ~only:(Plugin.get\_selection ()) p f ()

This statement only works if f gets only values of the command line options. If it tries to get the value of another state, the result is unspecified and all actions using any state of the current project and of project p also become unspecified.

## 4.12 Command Line Options

**Prerequisite:** knowledge of the OCaml module system.

Values associated with command line options are called *parameters*. The parameters of the Frama-C kernel are stored in module Parameters while the plug-in specific ones have to be defined in the plug-in source code.

In Frama-C, a parameter is actually a structure implementing signature Plugin.Parameter in order to handle projects: each parameter is indeed an internal state (see Section 4.11.5). Actually a bunch of signatures extended Plugin.Parameter are provided in order to deal with the usual parameter types. For example, there are signatures Plugin.INT and Plugin.BOOL for integer and boolean parameters. Mostly, these signatures provide getters and setters for parameters.

Implementing such an interface is very easy thanks to internal functors provided by the output module of **Plugin.Register**. Indeed, you have just to choose the right functor according to your option type and eventually the wished default value. Below is a list of most useful functors (see the signature **Plugin.General\_services** for an exhaustive list).

- 1. False (resp. True) builds a boolean option initialised to false (resp. true).
- 2. Int (resp. Zero) builds an integer option initialised to a specified value (resp. to 0).
- 3. String (resp. EmptyString ) builds a string option initialised to a specified value (resp. to the empty string "").
- 4. IndexedVal builds an option for any datatype  $\tau$  as soon as you provides a partial function from strings to value of type  $\tau$ .

Each functor takes as argument (at least) the name of the command line option corresponding to the parameter and a short description for this option.

**Example 4.26** The parameter corresponding to the option -occurrence of the plug-in occurrence is the module Print (defined in the file src/occurrence/options.ml). It is implemented as follow.

So it is a boolean parameter initialised by default to false. The declared interface for this module is simply

module Print: Plugin.INT

Another example is the parameter corresponding to the option -security-lattice of the plug-in security is the module Lattice (defined in the file src/security/options.ml). It is implemented as follow.

So it is a string parameter initialised by default to the string "weak". The field arg\_name is set to the empty string: so a default name for the argument of this option will be choose by Frama-C while displaying the help of this parameter. The field descr is the help message. The Interface for this module is simple:

module Lattice: Plugin.STRING

**Recommendation 4.3** Parameters of a same plug-in plugin should belong to a module called Options or Plugin\_options inside the plug-in directory.

Using a kernel parameters of a parameter of your own plug-in is very simple: you have simply to call the function **get** corresponding to your parameter.

**Example 4.27** To know whether Frama-C uses unicode, just write

Parameters.UseUnicode.get ()

Inside the plug-in From, just write

| From\_parameters.ForceCallDeps.get ()

in order to know whether callsite-wise dependencies has been required.

Using a parameter of a plug-in p outside p (for instance in another plug-in) requires the use of module Parameters.Dynamic because the module defining the parameter is not visible from the outside of its plug-in, so the option is accessible by any other plug-ins (and by the Frama-C kernel as well). Functions of sub-modules of module Parameters.Dynamic takes a string in argument which is the option name associated with the parameter.

Example 4.28 Outside the plug-in From, just write

| Parameters.Dynamic.Bool.get "-calldeps"

in order to know whether callsite-wise dependencies has been required.

# 4.13 Initialisation Steps

Prerequisite: knowledge of linking of OCaml files and OCaml labels.

In a standard way, Frama-C modules are initialised in the link order which remains mostly unspecified, so you have to use side-effects at module initialisation time carefully.

As side effects are sometimes useful, Frama-C provides some ways to put it at different initialisation times. For this purpose, the module Cmdline provides different functions to register an hook executed at different stages of the parsing of the Frama-C command line (see Section 4.11.5). Actually, the whole Frama-C initialisation process is enclosed in module Boot (the last linked module) which is the main entry point of Frama-C.

In order to clear what is done when  $\mathsf{Frama-C}$  is booting, we better specify the  $\mathsf{Frama-C}$  initialisation order below.

- 1. Running each Frama-C compilation unit in a mostly unspecified order. The only assumptions are the following:
  - the dependency order specified in the architecture overview (Figure 3.1, Section 3.1) is preserved;
  - for each plug-in p, the non-gui files of p are run before the the gui files of p (if any);
  - the file **src/kernel/bool.ml** is the last linked module.

In particular, the initialisation of the module **Cmdline** performs a very early parsing stage of the command line in order to detect the initial configuration. A plug-in developer cannot customize this parsing stage.

- 2. Starting the journal if required (see Section 4.9)
- 3. Creating the default project
- 4. Parsing each command line option register at the stage Cmdline.Extending.

- 5. Running each function registered through Cmdline.run\_after\_extending\_stage in an unspecified order. Most functions initialise postponed internal-state dependencies (see Section 4.11.5).
- 6. Parsing each command line option register at the stage Cmdline.Exiting.
- 7. Running each function registered through Cmdline.run\_after\_exiting\_stage in an unspecified order. These functions may stop Frama-C quickly.
- 8. Parsing each command line option register at the stage Cmdline.Loading.
- 9. Running each function registered through Cmdline.run\_after\_loading\_stage in an unspecified order. These functions set the initial stage of Frama-C.
- 10. Parsing each command line option register at the stage Cmdline.Configuring.
- 11. Running each function registered through Cmdline.run\_after\_configuring\_stage in an unspecified order. Usually these functions initialise plug-ins according to the arguments provided on the command line.
- 12. Running each function registered through Cmdline.run\_as\_the\_main in an unspecified order. Usually these functions are used in order to launch the right Frama-C entry point. For instance, one of them usually run each function registered through Db.Main.extendMain.extend.

# 4.14 Locations

**Prerequisite:** Nothing special (apart of core OCaml programming).

In Frama-C, different representations of C locations exist. Section 4.14.1 presents them. Moreover, maps indexed by locations are also provided. Section 4.14.2 introduces them.

#### 4.14.1 Representations

There are four different representations of C locations. Actually only three are really relevant. All of them are defined in module Locations. They are introduced below. See the documentation of src/memory\_state/locations.mli for details about the provided operations on these types.

- Type Location\_Bytes.t is used to represent values of C expressions like 2 or ((int) &a) + 13. With this representation, there is no way to know the size of a value while it is still possible to join two values. Roughly speaking it is represented by a mapping between C variable and offsets in bytes.
- Type location is used to represent the right part of a C affectation (including bitfields). It is represented by a Location\_Bits.t (see below) attached to a size. It is possible to join two locations *if and only if they have the same sizes*.
- Type Location\_Bits.t is similar to location\_Byte.t with offsets in bits instead of bytes. Actually it should only be used inside a location.

• Type Zone.t is a set of bits (without any specific order). It is possible to join two zones even if they have different sizes.

**Recommendation 4.4** Roughly speaking, locations and zones have the same purpose. You should use locations as soon as you have no need to join locations of different sizes. If you require to convert locations to zones, use function Locations.valid\_enumerate\_bits.

As join operators are provided for these types, they can be easily used in abstract interpretation analyses (which can themselves be implemented thanks to one of functors of module Dataflow, see Section 5.1.1).

## 4.14.2 Map Indexed by Locations

Modules Lmap and Lmap\_bitwise provide functors implementing maps indexed by locations and zones (respectively). The argument of these functors have to implement values attached to indices (locations or zones).

These implementations are quite more complex than simple maps because they automatically handle overlaps of locations (or zones). So such implementations actually require that structures implementing values attached to indices are lattices (*i.e.* implement signature Abstract\_interp.Lattice). For this purpose, functors of the abstract interpretation toolbox can help (see in particular module Abstract\_interp).

## 4.15 Visitors

**Prerequisite:** knowledge of OCaml object programming.

Cil offers a visitor, Cil.cilVisitor that allows to traverse (parts of) an AST. It is a class with one method per type of the AST, whose default behavior is simply to call the method corresponding to its children. This is a convenient way to perform local transformations over a whole Cil\_types.file by inheriting from it and redefining a few methods. However, the original Cil visitor is of course not aware of the internal state of Frama-C itself. Hence, there exists another visitor, Visitor.generic\_frama\_c\_visitor, which handles projects in a transparent way for the user. There are very few cases where the plain Cil visitor should be used.

Basically, as soon as the initial project has been built from the C source files (*i.e.* one of the functions File.init\_\* has been applied), only the Frama-C visitor should occur.

There are a few differences between the two (the Frama-C visitor inherits from the Cil one). These differences are summarized in Section 4.15.6, which the reader already familiar with Cil is invited to read carefully.

#### 4.15.1 Entry Points

Cil offers various entry points for the visitor. They are functions called Cil.visitCilAstType where astType is a node type in the Cil's AST. Such a function takes as argument an instance of a cilVisitor and an astType and gives back an astType transformed according to the visitor. The entry points for visiting a whole Cil\_types.file (Cil.visitCilFileCopy, Cil.visitCilFile and visitCilFileSameGlobals) are slightly different and do not support all kinds of visitors. See the documentation attached to them in cil.mli for more details.

## 4.15.2 Methods

As said above, there is a method for each type in the Cil AST (including for logic annotation). For a given type astType, the method is called  $vastType^{11}$ , and has type  $astType \rightarrow astType'$  visitAction, where astType' is either astType or astType list (for instance, one can transform a global into several ones). visitAction describes what should be done for the children of the resulting AST node, and is presented in the next section. In addition, there are two modes for visiting a varinfo: vvdec to visit its declaration, and vvrbl to visit its uses. More detailed information can be found in cil.mli.

For the Frama-C visitor, three methods, vstmt, vfile, and vglob take care of maintaining the coherence between the transformed AST and the internal state of Frama-C. Thus they must not be redefined. One should redefine vstmt\_aux and vglob\_aux instead.

## 4.15.3 Action Performed

The return value of visiting methods indicates what should be done next. There are four possibilities:

- SkipChildren the visitor do not visit the children;
- ChangeTo v the old node is replaced by v and the visit stops;
- DoChildren the visit goes on with the children; this is the default behavior;
- DoChildrenPost(v,f) the old node is replaced by v, the visit goes on with the children of v, and when it is finished, f is applied to the result.
- ChangeToPost(v,f) the old is replaced by v, and f is applied to the result. This is however not exactly the same thing as returning ChangeTo(f(v)). Namely, in the case of vstmt\_aux and vglob\_aux, f will be applied to v only *after* the operations needed to maintain the consistency of Frama-C's internal state with respect to the AST have been performed.

## 4.15.4 Visitors and Projects

The visitors takes an additional argument, which is the project in which the transformed AST should be put in. Note that an in-place visitor (see next section) should operate on the current project (otherwise, two projects would share the same AST). If this is not the case, it is up to the developer to ensure that the copy is done by other means, so that there is no sharing.

Note that the tables of the new project are not filled immediately. Instead, actions are queued, and performed when a whole Cil\_types.file has been visited. One can access the queue with the get\_filling\_actions method, and perform the associated actions on the new project with the fill\_global\_tables method.

 $<sup>^{11}{\</sup>rm This}$  naming convention is not strictly enforced. For instance the method corresponding to offset is voffs.

#### 4.15.5 In-place and Copy Visitors

The visitors take as argument a visitor\_behavior, which comes in two flavors: inplace\_visit and copy\_visit. In the in-place mode, nodes are visited in place, while in the copy mode, nodes are copied and the visit is done on the copy. For the nodes shared across the AST (varinfo, compinfo, enuminfo, typeinfo, stmt, logic\_info, predicate\_info and fieldinfo), sharing is of course preserved, and the mapping between the old nodes and their copy can be manipulated explicitly through the following functions:

- reset\_behavior\_name resets the mapping corresponding to the type name.
- get\_original\_name gets the original value corresponding to a copy (and behaves as the identity if the given value is not known).
- get\_name gets the copy corresponding to an old value. If the given value is not known, it behaves as the identity.
- **set**\_*name* sets a copy for a given value. Be sure to use it before any occurrence of the old value has been copied, or sharing will be lost.

get\_original\_name functions allow to retrieve additional information tied to the original AST nodes. Its result must not be modified in place (this would defeat the purpose of operating on a copy to leave the original AST untouched). Moreover, note that whenever the index used for name is modified in the copy, the internal state of the visitor behavior must be updated accordingly (via the set\_name function) for get\_original\_name to give correct results.

Туре	Index
varinfo	vid
compinfo	ckey
enuminfo	ename
typeinfo	tname
stmt	sid
logic_info	l_name
predicate_info	p_name
logic_var	lv_id
fieldinfo	fname and fcomp.ckey

The list of such indices is given Figure 4.2.

Figure 4.2: Indices of AST nodes.

Last, when using a copy visitor, the actions (see previous section) SkipChildren and ChangeTo must be used with care, *i.e* one has to ensure that the children are fresh. Otherwise, the new AST will share some nodes with the old one. Even worse, in such a situation the new AST might very well be left in an inconsistent state, with uses of shared node (e.g. a varinfo for a function f in a function call) which do not match the corresponding declaration <math>(e.g the GFun definition of f).

#### 4.15.6 Differences Between the Cil and Frama-C Visitors

As said in Section 4.15.2, vstmt and vglob should not be redefined. Use vstmt\_aux and vglob\_aux instead. Be aware that the entries corresponding to statements and globals in Frama-C tables are considered more or less as children of the node. In particular, if the method returns ChangeTo action (see Section 4.15.3), it is assumed that it has taken care of updating the tables accordingly, which can be a little tricky when copying a file from a project to another one. Prefer ChangeDoChildrenPost. On the other hand, a SkipChildren action implies that the visit will stop, but the information associated to the old value will be associated to the new one. If the children are to be visited, it is undefined whether the table entries are visited before or after the children in the AST.

#### 4.15.7 Example

Here is a small copy visitor that adds an assertion for each division in the program, stating that the divisor is not zero:

```
open Cil_types
open Cil
class non_zero_divisor prj = object(self)
  inherit Visitor.generic frama c visitor (Cil.copy visit()) prj
    (* A division is an expression: we override the vexpr method *)
    method vexpr = function
        \rm BinOp\,(\mbox{(Div}\,|\,Mod)\mbox{,\_,e2}\mbox{,\_})\ \rightarrow
           let t = Cil.typeOf e2 in
           let logic e2 =
            Logic const.mk dummy term
               (TCastE(t,Logic_const.expr_to_term e2)) t
          in
           let assertion = Logic const.prel (Rneq,logic e2,Cil.lzero()) in
           (* At this point, we have built the assertion we want to insert.
              It remains to attach it to the correct statement. The cil visitor
              maintains the information of which statement is currently visited
              in the current_stmt method, which returns None when outside
              of a statement, e.g. when visiting a global declaration. Here, it
              necessarily returns Some. *)
           let stmt = Extlib.the (self#current stmt) in
           (* Since we are copying the file in a new project, we can't insert
            the annotation into the current table, but in the table of the new
             project. To avoid the cost of switching projects back and forth,
             all operations on the new project are queued until the end of the
             visit, as mentioned above. This is done in the following
             statement. *)
          Queue.add
             (fun () \rightarrow Annotations.add assert stmt "before:true assertion)
             self#get_filling_actions;
           (* Do not forget to recurse on the children of the
              division. *)
           DoChildren
      | \rightarrow DoChildren (* do not do anything on other expressions
                             (except visiting their children)*)
end
(* This function returns a new project initialized with
the current file plus the annotations related to division. *)
let create_syntactic_check_project =
  File.create project from visitor
     "syntactic check"
     (new Syntactic check.non zero divisor);
```

# 4.16 GUI Extension

**Prerequisite:** *knowledge of* Lablgtk2.

Each plug-in can extend the Frama-C graphical user interface (aka *gui*) in order to support its own functionalities in the Frama-C viewer. For this purpose, a plug-in developer has to register a function of type Design.main\_window\_extension\_points -> unit thanks to Design.register\_extension. Design.main\_window\_extension\_points is a class type properly documented providing access to the main widgets of a Frama-C gui.

Such a code has to be put in separate files into the plug-in directory. Moreover, in Makefile.in, variable PLUGIN\_GUI\_CMO has to be set in order to compile the gui plug-in code (see Section 5.3.3).

Besides computations taking time have to call time to time function **!Db.progress** in order to keep the gui reactive.

Mainly that's all! The gui implementation uses Lablgtk2 [7]: so you can use any Lablgtk2compatible code in your gui extension. A complete exemple of gui extension may be found in plug-in Occurrence (see file src/occurrence/register\_gui.ml).

**Potential problems** All the gui plug-in extensions share the same window and same widgets. So conflicts can occur, especially if you specify some attributes on a predefined object. For example, if a plug-in wants to highlight a statement s in yellow and another one wants to highlight s in red at the same time, the behaviour is not specified but it could be quite difficult to understand for an user.

# 4.17 Documentation

**Prerequisite:** *knowledge of* ocamldoc.

Here we present some hints on the way to document your plug-in. First Section 4.17.1 introduces a quick general overview about the documentation process. Next Section 4.17.2 focus on the plug-in source documentation. Finally Section 4.17.3 explains how to modify the Frama-C website.

## 4.17.1 General Overview

Command make doc produces the whole Frama-C source documentation in HTML format. The generated index file is doc/code/html/index.html. A more general purpose index is doc/index.html (from which the previous index is accessible).

The previous command takes some times. So command make html only generates the kernel documentation (*i.e.* Frama-C without any plug-in) while make \$(PLUGIN\_NAME)\_DOC (by substituting the right value for \$(PLUGIN\_NAME)) generates the documentation for a single plug-in.

## 4.17.2 Source Documentation

Each plug-in should be properly documented. Frama-C uses ocamldoc and so you can write any valid ocamldoc comments.

The special tag  $\tt Qplugin\ developer\ guide\ must\ be\ attached\ to\ each\ function\ used\ in\ this\ document.$ 

First of all, a plug-in should export itself no function: the only visible plug-in interface should be in Db.

**Recommendation 4.5** To ensure this invariant, the best way is to provide an empty interface for the plug-in.

The interface name of a plug-in plugin must be Plugin.mli. Be careful to capitalisation of the filename which is unusual in OCaml but here required for compilation purpose.

Besides, the documentation generator also produces an internal plug-in documentation which may be useful for the plug-in developer itself. This internal documentation is available *via* file doc/code/plugin/index.html for each plug-in plugin. You can add an introduction to this documentation into a file. This file has to be assigned into variable PLUGIN\_INTRO of Makefile.in (see Section 5.3.3).

In order to ease the access to this internal documentation, you have to manually edit file doc/index.html in order to add an entry for your plug-in in the plug-in list.

## 4.17.3 Website

Target readers: developers with a CVS access.

The html sources of the Frama-C website belong to directory doc/www/src. Each plug-in available through the Frama-C website (http://www.frama-c.cea.fr) may have its own webpage.

For each plug-in p, the source of its webpage should be called p.prehtml: this file is preprocessed by the makefile generating the whole website. The format of this page looks like below.

```
<#head>
<h1>Impact plug-in</h1>
... Plug-in description ...
<#foot>
```

This page should be referenced from the page http://www.frama-c.cea.fr/plugins.html. For this purpose, you have to edit files plugins.prehtml and index.prehtml.

In order to generate the html pages from directory doc/www/src, just execute

\$ make

The generated website is available in directory doc/www/export and the homepage is doc/www/export/index.html.

The html pages belonging to directory doc/www/src must not be used in order to display the website because relative links are not the same than those of the real website. Use html pages of directory doc/www/export instead.

**Recommendation 4.6** You can use the address http://validator.w3.org/#validate\_ by\_upload in order to check the validity of your html code.

If you want to officially put the webpage on the Frama-C website, you have to contact CEA.

# 4.18 License Policy

Target readers: developers with a CVS access.

Prerequisite: knowledge of make.

If you want to redistribute a plug-in inside Frama-C, you have to define a proper license policy. For this purpose, some stuffs are provide in Makefile.in. Mainly we distinguish two cases described below.

• If the wished license is already used inside Frama-C , just extend the variable corresponding to the wished license in order to include files of your plug-in. Next run make headers.

**Example 4.29** Plug-in slicing is released under LGPL and is proprietary of both CEA and INRIA. So, in the makefile, there is the following line.

CEA\_INRIA\_LGPL= ... \ src/slicing\_types/\*.ml\* src/slicing/\*.ml\*

- If the wished license is unknown inside Frama-C, you have to:
  - 1. Add a new variable v corresponding to it and assign files of your plug-in;
  - 2. Extend variable LICENSES with this variable;
  - 3. Add a text file in directory licenses containing your licenses
  - 4. Add a text file in directory headers containing the headers to add into files of your plug-in (those assigned by v).

The filename must be the same than the variable name v. Moreover this file should contain a reference to the file containing the whole license text.

5. Run make headers.

# Chapter 5 Reference Manual

This chapter is a reference manual for plug-in developers. it provides full details which complete Chapter 4.

# 5.1 File Tree

This Section introduces main parts of Frama-C in order to quickly find useful information inside sources. Our goal is *not* to introduce the Frama-C software architecture (that is the purpose of Chapter 3) nor to detail each module (that is the purpose of the source documentation generated by make doc). Directory containing Cil implementation is detailed in Section 5.1.1 while directory containing the Frama-C implementation itself is presented in Section 5.1.2.

Kind	Name	Specification	Reference
	•	Frama-C root directory	
	src	Frama-C implementation	Section 5.1.2
Sources	cil	Cil source files	Section $5.1.1$
	external	Source of external free libraries	
Tests	tests	Frama-C test suites	Section $4.5$
C000	ptests	ptests implementation	
Generated Files	bin	Binaries	
Generated Piles	lib	Some compiled files	
	doc	Documentation directory	
Documentations	headers	Headers of source files	Section 4.18
	licenses	Licenses used by plug-ins and kernel	Section $4.18$
Shared libraries	share	Shared files	

Figure 5.1 shows directories useful for a plug-in developer. More details are provided below.

Figure 5.1: Frama-C directories.

- The Frama-C root directory contains the configuration files, the main Makefile Makefile.in and some information files (in uppercase).
- Frama-C sources are split in three directories: src (described in Section 5.1.2) contains the core of the implementation while cil (described in Section 5.1.1) and external

respectively contains the implementation of  $\mathsf{Cil}$  (extended with  $\mathsf{ACSL}$  ) and external libraries included in the  $\mathsf{Frama-C}$  distribution.

- Directory tests contains the Frama-C test suite which is used by tool ptests (see Section 4.5).
- Directories bin and lib contains binary files mainly produced by Frama-C compilation. Frama-C executables belong to directory bin, directories lib/plugins and lib/gui receives the compiled plug-ins and directory libfc received the compiled kernel interface. You should never add yourself any file in these directories.
- Documentations (including plug-in specific, source code and ACSL documentations) are provided in directory doc. Directories headers and licenses contains files useful for copyright notification (see Section 4.18).
- Directory share contains useful libraries for Frama-C users such as the Frama-C C library (e.g. ad-hoc libraries libc and malloc for Frama-C) and user-oriented Makefiles.

### 5.1.1 Directory cil

The source files of Cil belong to five directories shown Figure 5.2. More details are provided below.

Name	Specification
ocamlutil	OCaml useful utilities
src	Main Cil files
src/ext	Syntactic analysis provided by Cil
src/frontc	C frontend
<pre>src/logic</pre>	ACSL frontend

Figure 5.2: Cil directories.

- ocamlutil contains some OCaml utilities useful for a plug-in developer. Most important modules are Inthash and Cilutil. The first one contains an implementation of hashtables optimized for integer keys while the second one contains some useful functions (*e.g.* out\_some which extract a value from an option type) and datastructures (*e.g.* module StmtHashtbl implements hashtables optimized for statement keys).
- src contains the main files of Cil. Most important modules are Cil\_types and Cil. The first one contains type declarations of the Cil AST while the second one contains very useful operations over this AST.
- src/ext contains syntactic analysis provided by Cil. For example, module Cfg provides control flow graph, module Callgraph provides a syntactic callgraph and module Dataflow provides parameterised forward/backward data flow analysis.
- src/frontc is the C frontend which converts C code to the corresponding Cil AST. It should not be used by a Frama-C plug-in developer.

• src/logic is the ACSL frontend which converts logic code to the corresponding Cil AST. The only useful modules for a Frama-C plug-in developer are Logic\_const which provides some predefined logic constructs (terms, predicates, ...) and Logic\_typing which allows to dynamically extend the logic type system.

## 5.1.2 Directory src

The source files of Frama-C are split into different sub-directories inside src. Each subdirectory contains either a plug-in implementation or some parts of the Frama-C kernel.

Each plug-in implementation can be split into two different sub-directories, one for exported type declarations and related implementations visible from Db (see Chapter 3 and Section 4.10.1) and one-other for the implementation provided in Db.

Kind	Name	Specification	Reference
	kernel	Kernel toolbox	
Toolboxes	ai	Abstract interpretation toolbox	Section 4.14
	memory_states	Memory-state toolbox	Section 4.14
	project	Project library	Section 4.11
Libraries	lib	Miscellaneous libraries	
	misc	Additional useful operations	
Entry points	toplevel	Frama-C toplevel	Sections $4.13$ and $4.12$
	gui	Graphical User Interface	Section 4.16

Kernel directories are shown Figure 5.3. More details are provided below.

Figure	$5.3^{-1}$	Kernel	directories.
rigure	0.0.	TTELHEL	un ectories.

- Directory kernel contains the kernel toolbox over Cil. Main kernel modules are shown in Figure 5.4.
- Directories ai and memory\_states are the abstract interpretation and memory-state toolboxes (see section 4.14). In particular, in ai, module Abstract\_interp defines useful generic lattices and module Ival defines some pre-instantiated arithmetic lattices while, in memory\_states, module Locations provides several representations of C locations and modules Lmap and Lmap\_bitwise provide maps indexed by such locations.
- Directory project is the project library fully described in Section 4.11.
- Directories lib and misc contain datastructures and operations used in Frama-C. In particular, module Extlib is the Frama-C extension of the OCaml standard library whereas module Type is the interface for type values (the OCaml values representing OCaml types) required by dynamic plug-in registrations and uses and journalisation (see Section 4.8).
- Directory toplevel<sup>1</sup> contains the Frama-C toplevel. In particular, module Main defines the main Frama-C entry point (see Section 4.13).
- Directory gui<sup>1</sup> contains the gui implementation part common to all plug-ins. See Section 4.16 for more details.

<sup>&</sup>lt;sup>1</sup>From the outside, gui and toplevel may be seen as plug-ins with some exceptions because it has to be linked at the end of the link process.

Kind	Name	Specification	Reference
AST	Ast	The Cil AST for Frama-C	
ASI Ast_info		Operations over the Cil AST	
	File	AST creation and access to $C$ files	
Global	Globals	Operations on globals	
tables	Kernel_function	Operations on functions	
tables	Annotations	Operations on annotations	
	Loop	Operations on loops	
	Db	Static plug-in database	Section 4.10.1
Database	Db_types	Type declarations required by Db	Section $4.10.1$
Database	Dynamic	Interface for dynamic plug-ins	Section $4.10.2$
	Kui	High-level Frama-C front-end, quite deprecated	
	Config	Information about Frama-C version

Pretty	Ast_printer	Pretty-printers for AST node	
$\operatorname{printers}$	Printer	Main class for pretty-printing	
	Boot	Last linked module	Section 4.13
$\operatorname{Initializer}$	Gui_init	Very early initialisation of the GUI	Section $4.13$
	Special_hooks	Registration of kernel hooks	

# 5.2 Configure.in

Figure 5.5 presents the different parts of configure.in in the order that they are introduced in the file. The second row of the tabular says whether the given part has to be modified eventually by a kernel-integrated plug-in developer. More details are provided below.

Id	Name		Reference
1	Configuration of make	no	
2	Configuration of OCaml	no	
3	Configuration of mandatory tools/libraries	no	
4	Configuration of non-mandatory tools/libraries	no	
5	Platform configuration		
6	Wished Frama-C plug-in		Sections $4.2.2$ and $4.2.3$
7	Configuration of plug-in tools/libraries		Section $4.2.5$
8	Checking plug-in dependencies		Section $4.2.4$
9	Makefile creation		Section $4.2.2$
10	Summary		Section 4.2.2

- 1. Configuration of make checks whether the version of make is correct. Some useful option is -enable-verbosemake (resp. -disable-verbosemake) which set (resp. unset) the verbose mode for make. In verbose mode, right make commands are displayed on the user console: it is useful for debugging the makefile. In non-verbose mode, only command shortcuts are displayed for user readibility.
- 2. Configuration of OCaml checks whether the version of OCaml is correct.
- 3. Configuration of other mandatory tools/libraries checks whether all the external mandatory tools and libraries required by the Frama-C kernel are present.
- 4. Configuration of other non-mandatory tools/libraries checks which external nonmandatory tools and libraries used by the Frama-C kernel are present.
- 5. Platform Configuration sets the necessary platform characteristics (operating system, specific features of gcc, *etc*) for compiling Frama-C.
- 6. Wished Frama-C Plug-ins sets which Frama-C plug-ins the user wants to compile.
- 7. Configuration of plug-in tools/libraries checks the availability of external tools and libraries required by plug-ins for compilation and execution.
- 8. Checking Plug-in Dependencies sets which plug-ins have to be disable (at least partially) because they depend on others plug-ins which are not available (at least partially).
- 9. Makefile Creation creates Makefile from Makefile.in including information provided by this configuration.
- 10. Summary displays summary of each plug-in availability.

## 5.3 Makefiles

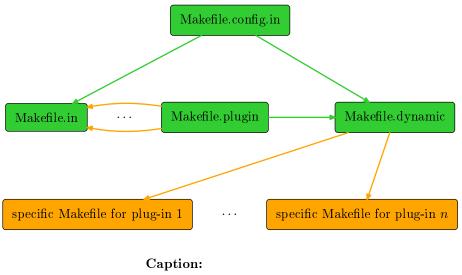

In this section, we detail the organization of the different Makefiles existing in Frama-C. First Section 5.3.1 presents a general overview. Next Section 5.3.2 details the different sections of Makefile.config.in and Makefile.in. Next Section 5.3.3 introduces variables customizing Makefile.plugin and Makefile.dynamic. Finally Section 5.3.4 shows specific details of Makefile.dynamic.

#### 5.3.1 Overview

Frama-C uses four different Makefiles if one excludes the plug-in specific ones. They are:

- Makefile.in: the general Makefile of Frama-C;
- Makefile.config.in: the Makefile configuring some general variables (especially the ones provided by configure) and setting some general rules;
- Makefile.plugin: the Makefile introducing specific stuff for plug-in compilation;
- Makefile.dynamic: the Makefile usable by plug-in specific Makefiles.

The three last ones are part of directory share of the Frama-C distribution. Each Makefile either includes or is included into at least another one. Figure 5.6 shows these inclusion relationship. Makefile.in and Makefile.dynamic are independent: the first one is used to

 $m1 \longrightarrow m2$  Makefile m1 is included into Makefile m2

Figure 5.6: Relationship between the Makefiles

compile the Frama-C kernel while the second one is used to compile the Frama-C plug-ins. Their common variables and rules are defined in Makefile.config.in. Makefile.plugin defines generic rules and variables for compiling plug-ins. It is used both by Makefile.in for kernel-specific plug-ins integrated compiled from the Frama-C Makefile and by Makefile.dynamic for plug-ins with their own Makefiles.

#### 5.3. MAKEFILES

## 5.3.2 Sections of Makefile.in and Makefile.config.in

Figure 5.7 presents the different parts of Makefile.config.in and Makefile.in in the order that they are introduced in these files. The third row of the tabular says whether the given part may be modified by a kernel-integrated plug-in developer. More details are provided below.

Id	Name	File	Mod.	Reference
1	Working directories	Makefile.config.in	no	
2	Installation paths	Makefile.config.in	no	
3	Ocaml stuff	Makefile.config.in	no	
4	Libraries	Makefile.config.in	no	
5	Miscellaneous	Makefile.config.in	no	
6	Verbosing	Makefile.config.in	no	
7	Shell commands	Makefile.config.in	no	
8	Command pretty printing	Makefile.config.in	no	
9	${ m Tests}$	Makefile.config.in	no	
10	Generic rules	Makefile.config.in	no	
11	Global plug-in variables	Makefile.in	no	
12	Additional global variables	Makefile.in	no	
13	Main targets	Makefile.in	no	
14	Coverage	Makefile.in	no	
15	O camlgraph	Makefile.in	no	
16	Frama-C Kernel	Makefile.in	no	
17	Plug-in sections	Makefile.in	YES	Section 4.3
18	Generic variables	Makefile.in	no	
19	$\operatorname{Toplevel}$	Makefile.in	no	
20	GUI	Makefile.in	no	
21	Standalone obfuscator	Makefile.in	no	
22	${ m Tests}$	Makefile.in	no	
23	Emacs tags	Makefile.in	no	
24	Documentation	Makefile.in	no	
25	Installation	Makefile.in	YES	<b>TODO:</b> not written yet
26	File headers: license policy	Makefile.in	YES	Section 4.18
27	Makefile rebuilding	Makefile.in	no	
28	$\operatorname{Cleaning}$	Makefile.in	no	
29	$\operatorname{Depend}$	Makefile.in	no	
30	ptests	Makefile.in	no	
31	Source distribution	Makefile.in	no	

Figure 5.7: Sections of Makefile.config.in and Makefile.in.

- 1. Working directories defines the main directories of Frama-C. In particular, it declares the variable UNPACKED\_DIRS which should be extended by a plug-in developer if he uses files which do not belong to the plug-in directory (that is if variable PLUGIN\_TYPES\_CMO is set, see Section 5.3.3).
- 2. Installation paths defines where Frama-C has to be installed.
- 3. Ocaml stuff defines the Objective Caml compilers and specific related flags.

- 4. Libraries defines variables for libraries required by Frama-C.
- 5. Miscellaneous defines some additional variables.
- 6. Verbosing sets how make prints the command. In particular, it defines the variable VERBOSEMAKE which must be set yes in order to see the right make commands in the user console. The typical use is
  - \$ make VERBOSEMAKE = yes
- 7. Shell commands sets all the shell commands eventually executed while calling make.
- 8. Command pretty printing sets all the commands to be used for pretty printing.

**Example 5.1** Consider the following target foo in a plug-in specific Makefile.

```
foo: bar
$(PRINT_CP) $@
$(CP) $< $@
```

Executing

```
$ make foo
```

prints

```
| Copying to foo
```

while executing

\$ make foo VERBOSEMAKE=yes

prints | cp -f bar foo

If one of the two commands is missing for the target foo, either make foo or make foo VERBOSEMAKE=yes will not work as expected.

- 9. Tests defines a generic templates for testing plug-ins.
- 10. Generic rules contains rules in order to automatically produces different kinds of files (*e.g.* .cm[iox] from .ml or .mli for Objective Caml files)
- 11. Global plug-in variables declares some plug-in specific variables used throughout the makefile.
- 12. Additional global variables declares some other variables used throughout the makefile.
- 13. Main targets provides the main rules of the makefile. The most important ones are top, byte and opt which respectively build the Frama-C interactive, bytecode and native toplevels.
- 14. Coverage defines how compile this library.
- 15. Ocamlgraph defines how compile this library.
- 16. Frama-C Kernel provides variables and rules for the Frama-C kernel. Each part is described in specific sub-sections.

- 17. After Section "Kernel", there are several sections corresponding to **plug-ins** (see Section 5.3.3). This is the part that a plug-in developer has to modify in order to add compilation directives for its plug-in.
- 18. Generic variables provides variables containing files to be linked in different contexts.
- 19. Toplevel provides rules for building the files of the form bin/toplevel.\*.
- 20. GUI provides rules for building the files of the form bin/viewer.\*
- 21. Standalone obfuscator provides rules for building the Frama-C obfuscator.
- 22. Tests provides rules to execute tests (see Section 4.5).
- 23. Emacs tags provides rules which generate emacs tags (useful for a quick search of OCaml definitions).
- 24. Documentation provides rules generating Frama-C source documentation (see Section 4.17).
- 25. Installation provides rules for installing different parts of Frama-C.
- 26. File headers: license policy provides variables and rules to manage the Frama-C license policy (see Section 4.18).
- 27. Makefile rebuilding provides rules in order to automatically rebuild Makefile and configure when required.
- 28. Cleaning provides rules in order to remove files generated by makefile rules.
- 29. Depend provides rules which compute Frama-C source dependencies.
- 30. Ptests provides rules in order to build ptests (see Section 4.5).
- 31. Source distribution provides rules usable for distributing Frama-C.

#### 5.3.3 Variables of Makefile.dynamic and Makefile.plugin

Figures 5.8 and 5.9 presents all the variables that can be set before including Makefile.plugin or Makefile.dynamic (see Sections 4.3 and 4.4). The last column is set to *no* if and only if the line is not relevant for a standard plug-in developer. Details are provided below.

• Variable PLUGIN\_NAME is the module name of the plug-in.

So it must be capitalised (as each OCaml module name).

- Variable PLUGIN\_DIR is the directory containing plug-in source files. It is usually set to src/plugin where plugin is the plug-in name.
- Variable PLUGIN\_ENABLE must be set to yes if the plug-in has to be compiled. It is usually set to **@**plugin\_ENABLE@ provided by configure.in where plugin is the plug-in name.
- Variable PLUGIN\_DYNAMIC must be set to yes if the plug-in has to be dynamically linked with Frama-C.

Kind	Name	Specification	
Usual information	PLUGIN_NAME	Module name of the plug-in	
	PLUGIN_DIR	Directory containing plug-in source	no
		files	
	PLUGIN_ENABLE	Whether the plug-in has to be com-	no
		piled	
	PLUGIN_DYNAMIC	Whether the plug-in is dynamically	no
		linked with Frama-C	
	PLUGIN_HAS_MLI	Whether the plug-in gets an interface	
Source files	PLUGIN_CMO	.cmo plug-in files	
	PLUGIN_CMI	.cmi plug-in files without correspond-	
		ing .cmo	
	PLUGIN_TYPES_CMO	.cmo plug-in files not belonging to	
		\$(PLUGIN_DIR)	
	PLUGIN_GUI_CMO	.cmo plug-in files not belonging to	
		\$(PLUGIN_DIR)	
	PLUGIN_BFLAGS	Plug-in specific flags for ocamlc	
	PLUGIN_OFLAGS	Plug-in specific flags for ocamlopt	
Compilation	PLUGIN_LINK_BFLAGS	Plug-in specific flags for linking with	
flags		ocamlc	
	PLUGIN_LINK_OFLAGS	Plug-in specific flags for linking with	
		ocamlopt	
	PLUGIN_LINK_GUI_BFLAGS	Plug-in specific flags for linking a GUI	
		with ocamlc	
	PLUGIN_LINK_GUI_OFLAGS	Plug-in specific flags for linking a GUI	
		with ocamlopt	

Figure 5.8: Standard parameters of Makefile.dynamic and Makefile.plugin.

#### 5.3. MAKEFILES

- Variable PLUGIN\_HAS\_MLI must be set to yes if plug-in *plugin* gets a file .mli (which must be capitalised: Plugin.mli, see Section 4.17) describing its API. Note that this API should be empty in order to enforce the architecture invariant which is that each plug-in is used through Db (see Chapter 3).
- Variables PLUGIN\_CMO and PLUGIN\_CMI are respectively .cmo plug-in files and .cmi files without corresponding .cmo plug-in files. For each of them, do not write their file path nor their file extension: they are automatically added (\$(PLUGIN\_DIR)/f.cm[io] for a file f).
- Variable PLUGIN\_TYPES\_CMO is the .cmo plug-in files which do not belong to \$(PLUGIN\_DIR). They usually belong to src/plugin\_types where plugin is the plug-in name (see Section 4.10.1). Do not write file extension (which is .cmo): it is automatically added.
- Variable PLUGIN\_GUI\_CMO is the .cmo plug-in files which have to be linked with the GUI (see Section 4.16). As for variable PLUGIN\_CMO, do not write their file path nor their file extension.
- Variables of the form PLUGIN\_\*\_FLAGS are plug-in specific flags for ocamlc, ocamlopt, ocamldep or ocamldoc.
- Variable PLUGIN\_GENERATED is files which must be generated before computing plugin dependencies. In particular, this is where .ml files generated by ocamlyacc and ocamllex must be placed if needed.
- Variable PLUGIN\_DEPENDS is the other plug-ins which must be compiled before the considered plug-in. Note that, in a normal context, it should not be used because a plug-in interface should be empty (see Chapter 3).
- Variable PLUGIN\_UNDOC is the source files for which no documentation is provided. Do not write their file path which is automatically set to \$(PLUGIN\_DIR).
- Variable PLUGIN\_TYPES\_TODOC is the additional source files to document with the plugin. They usually belong to src/plugin\_types where plugin is the plug-in name (see Section 4.10.1).
- Variable PLUGIN\_INTRO is the text file to append to the plug-in documentation introduction. Usually this file is doc/code/intro\_plugin.txt for a plug-in plugin. It can contain any text understood by ocamldoc.
- Variable PLUGIN\_HAS\_EXT\_DOC is set to yes if the plug-in has its own reference manual. It is supposed to be a pdf file generated by make in directory doc/\$(PLUGIN\_NAME)
- Variable PLUGIN\_NO\_TEST must be set to yes if there is no specific test directory for the plug-in.
- Variable PLUGIN\_TESTS\_DIRS is the directories containing plug-in tests. Its default value is tests/\$(notdir \$(PLUGIN\_DIR))).
- Variable PLUGIN\_TESTS\_LIB is the .cmo plug-in specific files used by plug-in tests. Do not write its file path (which is \$(PLUGIN\_TESTS\_DIRS)) nor its file extension (which is .cmo).

Kind	Name	Specification	
	PLUGIN_DEPFLAGS	Plug-in specific flags for ocamldep	
Dependencies	PLUGIN_GENERATED	Plug-in files to compiled before	
		running ocamldep	
	PLUGIN_DEPENDS	Other plug-ins to compiled before	no
		the considered one	
	PLUGIN_DOCFLAGS	Plug-in specific flags for ocamldoc	
	PLUGIN_UNDOC	Source files with no provided doc-	
Documentation		umentation	
	PLUGIN_TYPES_TODOC	Additional source files to docu-	
		ment	
	PLUGIN_INTRO	Text file to append to the plug-in	
		introduction	
	PLUGIN_HAS_EXT_DOC	Whether the plug-in has an exter-	
		nal pdf manual	
	PLUGIN_NO_TESTS	Whether there is no plug-in spe-	
		cific test directory	
Testing	PLUGIN_TESTS_DIRS	tests to be included in the default test suite	
	PLUGIN_TESTS_DIRS_DEFAULT	Directories containing tests	
	PLUGIN_TESTS_LIBS	Specific .cmo files used by plug-in	
		tests	
	PLUGIN_NO_DEFAULT_TEST	Whether to include tests in default	
		test suite.	
	PLUGIN_DISTRIBUTED_BIN	Whether to include the plug-in in	no
Distribution		binary distribution	
	PLUGIN_DISTRIBUTED	Whether to include the plug-in in	no
		source distribution	
	PLUGIN_DISTRIB_EXTERNAL	Additional files to be included in	no
		the distribution	

Figure 5.9: Special parameters of Makefile.dynamic and Makefile.plugin.

- Variable PLUGIN\_NO\_DEFAULT\_TEST indicates whether the test directory of the plug-in should be considered when running Frama-C default test suite. When set to a non-empty value, the plug-in tests are run only through make \$(PLUGIN\_NAME)\_tests.
- Variable PLUGIN\_DISTRIB\_BIN indicates whether the plug-in should be included in a binary distribution.
- Variable PLUGIN\_DISTRIBUTED indicates whether the plug-in should be included in a source distribution.
- Variable PLUGIN\_DISTRIB\_EXTERNAL is the list of files that should be included in the source distribution for this plug-in, outside of the src/\$(PLUGIN\_NAME) directory (and the test and documentation directories if any).

As previously said, the above variables is set before including Makefile.plugin in order to customize its behavior. Nevertheless they must not be use anywhere else in the makefile. In order to deal with this issue, for each plug-in p, Makefile.plugin provides some variables which may be used after its inclusion defining p. These variables are listed in Figure 5.10. For each variable of the form  $p_VAR$ , its behavior is exactly equivalent to the value of the parameter PLUGIN\_VAR for the plug-in  $p^2$ .

Kind	Name <sup>3</sup>
Usual information	plugin_DIR
	plugin_CMO
	$plugin\_\texttt{CMI}$
Source files	$plugin\_\texttt{CMX}$
	$plugin\_{\tt TYPES\_CMO}$
	$plugin\_{\tt TYPES\_CMX}$
	$plugin\_{\tt BFLAGS}$
	$plugin\_{\tt OFLAGS}$
Compilation flags	$plugin\_LINK\_BFLAGS$
	$plugin\_LINK\_OFLAGS$
	plugin_LINK_GUI_BFLAGS
	$plugin\_LINK\_GUI\_OFLAGS$
Dependencies	$plugin\_{\tt DEPFLAGS}$
Dependencies	$plugin\_\texttt{GENERATED}$
Documentation	plugin_DOCFLAGS
	$plugin\_\texttt{TYPES}\_\texttt{TODOC}$
Testing	plugin_TESTS_DIRS
Testing	$plugin\_\texttt{TESTS\_LIB}$

Figure 5.10: Variables defined by Makefile.plugin.

### 5.3.4 Makefile.dynamic

**TODO:** not written yet

<sup>&</sup>lt;sup>2</sup>Variables of the form  $p_*CMX$  have no PLUGIN\_\*CMX counterpart but their meanings should be easy to understand.

<sup>&</sup>lt;sup>3</sup> plugin is the module name of the considered plug-in (*i.e.* as set by  $(PLUGIN_NAME)$ ).

## 5.4 Testing

Section 4.5 explains how to test a plug-in. Here Figure 5.11 details the options of ptests while Figure 5.12 shows all the directives that can be used in a configuration headers of a test (or a test suite). Some details about them are provided below.

kind	Name	Specification	Default
	-add-options	Additional options passed to the	
Toplevel		toplevel	
	-byte	Use bytecode toplevel	no
	-opt	Use native toplevel	yes
Behavior	-run	Delete current results; run tests and	yes
		examine results	
	-examine	Only examine current results; do not	no
		run tests	
	-show	Run tests and show results, but do	no
		not examine them; implies -byte	
	-update	Take current results as new oracles;	no
		do not run tests	
	-exclude suite	Do not consider the given suite	
Misc.	-diff cmd	Use cmd to show differences between	diff -u
WHSC.		results and oracles when examining	
		$\operatorname{results}$	
	-cmp cmd	Use cmd to compare results against	cmp -s
		oracles when examining results	
	-use-diff-as-cmp	Use the same command for diff and	no
		cmp	
	-j n	Set level of parallelism to <b>n</b>	4
	- V	Increase verbosity (up to twice)	0
	-help	Display helps	no

Figure 5.11: ptests options.

The commands provided through the -diff and -cmp options play two related but distinct roles. cmp is always used for each test (in fact it used twice: one for the standard output and one for the error output). Only its exit code is taken into account by ptests and the output of cmp is discarded. An exit code of 1 means that the two files have differences. The two files will then be analyzed by diff, whose role is to show the differences between the files. An exit code of 0 means that the two files are identical. Thus, they won't be processed by diff. An exit code of 2 indicates an error during the comparison (for instance because of the corresponding oracle does not exist). Any other exit code results in a fatal error. It is possible to use the same command for both cmp and diff with the -use-diff-as-cmp option, which will take as cmp command the command used for diff.

The **-exclude** option can take as argument a whole suite or an individual test. It can be used with any behavior.

Any directive can identify a file using a relative path. The default directory considered for . is always the parent directory of directory tests. The DONTRUN directive does not need to have any content, but it is useful to provide an explanation of why the test should not be

Kind	Name	Specification	default
Command	CMD	Program to run	./bin/toplevel.opt
	OPT	Options given to the program	-val -out -input -deps
	STDOPT	Add and remove options from	None
		the default set	
	EXECNOW	Run a command before the	None
		test	
	FILTER	Command used to filter re-	None
		sults	
Test suite	DONTRUN	Do not execute this test	None
	FILEREG	selects the files to test	.*\.\(c i\)
Miscellaneous	COMMENT	Comment in the configuration	None
	GCC	Unused (compatibility only)	None

Figure 5.12: Directives in configuration headers of test files.

run (e.g test of a feature that is currently developed and not fully operational yet). If a test file is explicitly given on the command line of **ptests**, it is always executed, regardless of the presence of a DONTRUN directive.

As said in Section 4.5.2, these directives can be found in different places:

- 1. default value of the directive (as specified in Fig. 5.12);
- 2. inside file tests/test\_config;
- 3. inside file tests/subdir/test\_config (for each sub-directory subdir of tests); or
- 4. inside each test file

As presented in Section 4.5.3, alternative directives for test configuration <special\_name> can be found in slightly different places:

- default value of the directive (as specified in Fig. 5.12);
- inside file tests/test\_config\_<special\_name>;
- inside file tests/subdir/test\_config\_<special\_name> (for each sub-directory subdir of tests); or
- inside each test file.

For a given test tests/suite/test.ml, each existing file in the sequence above is read in order and defines a configuration level (the default configuration level always exists).

• At a given configuration level, the default value for directive CMD is the last CMD directive of the preceding configuration level. Each directive CMD is used only with the next directive OPT or STDOPT. No test case is generated if there is no further OPT directive. Following OPT or STDOPT directives are applied on the default program until another directive CMD is given.

#### CHAPTER 5. REFERENCE MANUAL

- If there are several directives OPT in the same configuration level, they correspond to different test cases. The OPT directive(s) of a given configuration level replace(s) the ones of the preceding level.
- The STDOPT directive takes as default set of options the last OPT directive of the preceding configuration level. The syntax for this directive is the following.

```
STDOPT: [[+-]"opt" ...]
```

options are always given between quotes. An option following a + is added to the current set of options while an option following a - is removed from it. The directive can be empty (meaning that the corresponding test will use the standard set of options). As with OPT, each STDOPT corresponds to a test case.

• The syntax for directive **EXECNOW** is the following.

```
EXECNOW: [ [ LOG file | BIN file ] ... ] cmd
```

Files after LOG are log files generated by command cmd and compared from oracles, whereas files after BIN are binary files also generated by cmd but not compared from oracles. Full access path to these files have to be specified only in cmd. All the commands described by directives EXECNOW are executed in order and before running any of the following tests. EXECNOW directives from a given level are added to the directives from preceding levels.

• FILEREG directive contains a regular expression indicating which files in the directory containing the current test suite are actually part of the suite. This directive is only usable in a test\_config configuration file.

# Appendix A Changes

This chapter summarizes the changes in this documentation in each Frama-C release. First we list changes of the last release.

We list changes of previous releases below.

- Initialisation Steps: update according to the new implementation
- Command Line Options: update according to the new implementation
- Plug-in General Services: fully new section introducing the new module Plugin
- File Tree: update according to changes in the kernel
- Makefiles: update according to the new file Makefile.dynamic and the new file Makefile.config.in
- Architecture: update according to the recent implementation changes
- Tutorial: update according to API changes and the new way of writting plug-ins
- configure.in: update according to changes in the way of adding a simple plug-in
- Plug-in Registration and Access: update according to the new API of module Type

## Lithium-20081201

- Changes: fully new appendix
- Command Line Options: new sub-section Storing New Dynamic Option Values
- Configure.in: compliant with new implementations of configure\_library and configure\_tool
- Exporting Datatypes: now embedded in new section Plug-in Registration and Access
- GUI: update, in particular the full example has been removed
- Introduction: improved
- Plug-in Registration and Access: fully new section

- **Project**: compliant with the new interface
- **Reference Manual**: integration of dynamic plug-ins
- Software architecture: integration of dynamic plug-ins
- Tutorial: improve part about dynamic plug-ins
- Tutorial: use Db.Main.extend to register an entry point of a plug-in.
- Website: better highlighting of the directory containing the html pages

## Lithium-20081002+beta1

- **GUI**: fully updated
- **Testing**: new sub-section Alternative testing
- Testing: new directive STDOPT
- Tutorial: new section Dynamic plug-ins
- Visitor: ChangeToPost in sub-section Action Performed

## Helium-20080701

- **GUI**: fully updated
- Makefile: additional variables of Makefile.plugin
- **Project**: new important note about registration of internal states in Sub-section *Internal State: Principle*
- Testing: more precise documentation in the reference manual

## Hydrogen-20080502

- **Documentation**: new sub-section *Website*
- Documentation: new ocamldoc tag @plugin developer guide
- Index: fully new
- **Project**: new sub-section Internal State: Principle
- Reference manual: largely extended
- Software architecture: fully new chapter

## Hydrogen-20080501

• First public release
