

Code analysis with Frama-C Value Analysis

Stance Training Session – Course 1

Virgile Prevosto

March 28th, 2013

long ra
t for 0 =>
ct); if (m
tmp2 =
se of the

tmp2[0] = 1; /* (Nb) - 1) else if (tmp1[0] >= 1) /* (Nb) - 1) else tmp2[0] = tmp1[0]; /* Then the second part looks like the first one: tmp1[0][k] = 0; k = 0, k-1) tmp1[0][k] += mc2[0][k] * tmp2[0][k]; /* The [i][j] coefficient of the matrix product MC2*TMP2, that is: *MC2*(TMP1) = MC2*(MC1*M1) = MC2*M1 *MC1
l = 1; tmp1[0][0] >= 1; /* Final rounding: tmp2[0][0] is now represented on 9 bits: *if (tmp1[0][0] < -256) m2[0][0] = -256; else if (tmp1[0][0] > 255) m2[0][0] = 255; else tmp2[0][0] = tmp1[0][0];

Introduction

Abstract domains

- Arithmetic
- Memory

Methodology

- Basic commands
- Parameters

Extensions

`(long n)`
`for (i = 0; i < n; i++)`
`if (i % 2 == 0)`
`tmp2 =`
`...`
`...`

`tmp2[i] = (i < (n-1)) ? tmp1[i] : (i < (n-1) ? tmp1[i] : 1);` Then the second part takes the first one: `tmp1[i] = 0; k = 0; k++ tmp1[k] += mc2[i][k] * tmp2[k];` The [i][j] coefficient of the matrix product MC2*TMP2, that is: *MC2*(TMP1) = MC2*(MC1*M1) = MC2*M1*MC1
`l = 1; tmp1[i][l] += 1;` Final rounding: `tmp2[i] is now represented on 9 bits: *if (tmp1[i] < -256) m2[i] = -256; else if (tmp1[i] > 255) m2[i] = 255; else m2[i] = tmp1[i];`

Value Analysis Plugin

Credits

- ▶ Pascal Cuoq
- ▶ Boris Yakobowski

Find the domains of the variables of a program

- ▶ based on **abstract interpretation**
- ▶ **alarms** on operations that **may** be invalid
- ▶ alarms on the specifications that may be invalid
- ▶ **Correct**: if no alarm is raised, no runtime error can occur
- ▶ can also be used in interpreter mode

long n;
for (i = 0; i < n; i++)
 tmp2[i] =
 ... of the

tmp2[0] = 1; for (i = 1; i < n; i++) tmp2[i] = tmp2[i-1] * i; // This is the second part of the first part of the program.
tmp1[0] = 0; for (k = 0; k < n; k++) tmp1[k] = mc2[0][k] * tmp2[k]; // The [i][j] coefficient of the matrix product MC2*TMP2, that is, *MC2*(TMP1) = MC2*(MC1*M1) = MC2*M1 * MC1
i = 1; tmp1[0][i] >>= 1; // Final rounding: tmp2[0][i] is now represented on 9 bits. if (tmp1[0][i] < -256) tmp2[0][i] = -256; else if (tmp1[0][i] > 255) tmp2[0][i] = 255; else tmp2[0][i] = tmp1[0][i];

Some specificities

- ▶ Precise handling of **pointers**
- ▶ Several representation for dynamic allocation (precision vs. time)
- ▶ GUI: can show possible values of any location at any program point.
- ▶ time and memory efficient (as much as achievable)
- ▶ Precise enough
 - ▶ for proving absence of runtime errors on some critical code
 - ▶ to serve as a back-end for other semantical analyzes through its API

long n
for 0 <=
c1[0] m
tmp2
of d

tmp2[0] = 0; for (k = 0; k < n; k++) tmp1[k] = m2[0][k] * tmp2[k]; // The [0] coefficient of the matrix product MC2*TMP2, that is * MC2[0](TMP1) = MC2[0](MC1*M1) = MC2[0]1 * MC1[0]1 + MC2[0]2 * MC1[0]2 + ... + MC2[0]n * MC1[0]n >= 1. Final rounding: tmp2[0] is now represented on 3 bits: if (tmp1[0] < -255) tmp2[0] = -255; else if (tmp1[0] > 255) tmp2[0] = 255; else tmp2[0] = tmp1[0];

Integer and Floating Point Arithmetic

Corresponding Abstract Domain

small set of integers (by default, cardinal ≤ 8)

- ⊕ integer interval \times modulo information
- ⊕ finite floating-point interval

Examples

- ▶ $\{0; 40; \}$ = 0 or 40
- ▶ $[0..40]$ = an integer between 0 and 40 (inclusive)
- ▶ $[-..-]$ = any integer (within the bound of the corresponding integral type)
- ▶ $[3..39], 3\%4$ = 3, 7, 11, 15, 19, 23, 27, 31, 35 or 39
- ▶ $[0.25..3.125]$ = floating-point between 0.25 et 3.125 (inclusive)

Base Address

Global variable

- ⊕ Formal parameter of main function
- ⊕ literal string constant
- ⊕ NULL
- ⊕ ...

Addresses

- ▶ Base address \rightarrow arithmetic value
- ▶ Functional abstract domain
- ▶ Equivalent to an associative *map*
- ▶ can be used as a rvalue for any type
- ▶ Pointer to integer cast will loose precision

Examples of Addresses

Precise Base

- ▶ $\{\{\&p + \{4; 8\}\}\}$ = address of p shifted from 4 or 8 octets
- ▶ $\{\{\&"foobar";\}\}$ = Address of literal string "foobar" (shifted from 0)
- ▶ $\{\{\&NULL + \{1024;\}\}\}$ = Absolute location 1024

Imprecision

- ▶ garbled mix of $\&\{x_1; \dots; x_n\}$ = unknown address built upon arithmetic operations over integers and addresses $x_1; \dots; x_n$.
- ▶ **ANYTHING** = top of the lattice. Should not occur in practice

Write to an Address

Abstract Domain

written address = valid left value

address

- × initialized?
- × *not dangling pointer?*

Exemple

```

{
    int x, y;
    if (e) x = 2;
L: if (e) y = x + 1;
}
  
```

- ▶ At *L*, we know that *x* equals 2 iff it has been initialized
- ▶ Depending on the complexity of *e*, we know that *y* equals 3 if *x* equals 2

Concrete Memory

- ▶ Seen as big array of bits
- ▶ read/write a value v at address $i =$ read/write v at index i over n bits.
- ▶ n depends upon the type of v
- ▶ potential **overlap**
- ▶ **example:** $x.a$ extends over n bits, $x.b$ over m bits. Writing at $x.a$ over p bytes with $n < p < m$ will partially erase $x.b$

Contiguous Memory Zones

offsetmap = interval \mapsto value

Example

First 32 bits contain address of x , next 16 contain 12.

- $[0..31] \mapsto \{\{\&x \text{ (initialized, *not dangling*)}\}\}$
- $[32..47] \mapsto 12$

Remark

- ▶ Integers and pointers share the same representation
- ▶ Values in memory can be integers
- ▶ $12 \triangleq \text{NULL} \mapsto 12$ (initialized, *not dangling*)

Abstract Memory State

base address \rightarrow offsetmap

Example

$$S \mapsto \{ [0..31] \mapsto \{ \&x \mapsto 0 \text{ (initialized, not dangling)} \}$$

$$[32..47] \mapsto \{ \text{NULL} \mapsto 12 \text{ (initialized, not dangling)} \} \}$$

$$x \mapsto \{ [0..31] \mapsto \{ \text{NULL} \mapsto \{ 3; 24 \} \text{ (initialized, not dangling)} \} \}$$

Displaying Values

- ▶ **Expected type** is used to display values

Exemple

$$S.\text{mypointer} \in \{ \{ \&x \} \}$$

$$.\text{myshort} \in 12$$

$$x \in \{ 3; 24 \}$$

Abstract Memory and Overlapping

```
int c, x;
char t[6];

void test(void) {
    t[0] = c ? 1 : 2;
    *(int*)(t+1) = c ? 3 : 4;
    *(t+3) = 5;
    x = *(int*)(t+1);
}
```

Main options

- ▶ `-main`: specifies the entry point of the analysis (default: `main` function)
- ▶ `-lib-entry`: Library mode: globals are not assumed to be 0-initialized
- ▶ `-val`: launch value, starting at the specified entry point

`abs.c`

```
int R;
void abs(int x) {
    R = x >= 0 ? x : -x;
}
```

▶ `frama-c -main abs -val -lib-entry abs.c`

Is abstract interpretation an automated plug-in?

- ▶ yes...
- ▶ and no!
- ▶ **must be driven** carefully to give meaningful results
- ▶ requires some expertise and some time

Another example

`simple.c` (`frama-c -val simple.c`)

```

int S=0;

int T[5];

int main(void) {
    int i;
    int *p = &T[0] ;
    for (i = 0; i < 5; i++) {
        S = S + i; *p++ = S;
    }
    return S;
}
  
```

Get feedback from Value Analysis

- ▶ with the GUI
- ▶ with `Frama_C_show_each_test(...)`
- ▶ with `Frama_C_dump_each()`

```

long n;
for (n = 0; n < 10; n++)
  tmp2 =
  // ...

```

```

tmp2[i][j] = (i < (n-1) ? tmp2[i][j] : (i < (n-1) ? tmp2[i][j] : tmp2[i][j]); // Then the second part takes the first part
tmp2[i][j] = 0; k = 8; k--> tmp2[i][j] += mc2[i][k] * tmp2[k][j]; // The [i][j] coefficient of the matrix product MC2*TMP2, that is *MC2*(TMP1) = MC2*(MC1*M1) = MC2*M1*MC1
i = i + 1; tmp2[i][j] >= 255 ? Final rounding: tmp2[i][j] is now represented on 9 bits: if (tmp2[i][j] < -256) tmp2[i][j] = -256; else if (tmp2[i][j] > 255) tmp2[i][j] = 255;

```

Help Value Analysis to Understand the Code

- ▶ Pay attention to **missing code** (external library) or code that is **not understood** (asm)
 - ▶ write **C code** (stub), that can be understood by Value and approximates the missing part well enough with respect to the desired property
 - ▶ give an **ACSL specification**
- ▶ Give an appropriate **context**
 - ▶ Write an appropriate **entry point** to initialize global variables and formal parameters
 - ▶ Sometime possible to use **dedicated options** (`-context-*`)

long n;
for (i = 0; i < n; i++)
 tmp2[i] = 0;
 ...

tmp2[0] = 0; for (k = 0; k < n; k++) tmp1[k] = mc2[0][k] * tmp2[k]; /* The [0] coefficient of the matrix product MC2 * TMP2, that is, * MC2[0](TMP2) = MC2[0](MC1 * M1) = MC2[0]M1 = MC2[0]M1[0] >= 0. */ Final rounding: tmp2[0] is now represented on 3 bits: if (tmp1[0] < 256) tmp2[0] = 256; else if (tmp1[0] > 255) tmp2[0] = 255; else tmp2[0] = tmp1[0];

Enhance precision

Loops

- ▶ option `-ulevel`: syntactic loop unrolling
- ▶ option `-slevel`: allows Value to explore n separated paths before joining them
- ▶ option `-wlevel`: number of loop steps before performing widening (default is 3, use with caution)

Driving Value through Annotations

- ▶ **ACSL assertions** can be used to restrict propagated domains
- ▶ but only if Value can interpret it

```
/*@ assert x % 2 == 0; */
```

```
// potentially useful
```

```
/*@ assert \exists integer y; x == 2 * y; */
```

```
// useless
```

- ▶ Case analysis using **disjunctions**

Plugins based on Value

- ▶ Lightweight Analyzers
 - ▶ Call graphs
 - ▶ Constant propagation
 - ▶ Occurrence

- ▶ Side Effects and Dependencies
 - ▶ Functional dependencies
 - ▶ Imperative effects
 - ▶ Operational effects
 - ▶ Scope of assignments

- ▶ Code specialization
 - ▶ Slicing
 - ▶ Sparecode
 - ▶ Impact
